Hi,

Quote:
I sniff with tcpdump but this is hard because I don't know when the container will be down.

at the moment everything is fine and I can't see anything strange in provided output. So you'd better catch a moment when a particular VE is down and then:

- compare the provided output with output that will be at that moment (or just post it here)
- run tcpdump on eth0 and venet0 interfaces on the HN as well as on the venet0 interface inside the VE
- check sysctls http://wiki.openvz.org/Quick_installation#sysctl
- check routes/iptables inside the VE

P.S. BTW, who writes "Down Hosts"? What kind of program puts that messages in logs and how it indicates that hosts are really down?
