Subject: Container broken after migration

Hi everybody,

I am facing an annoying problem. When I migrate a container from one hardware node to another more recent(using virtuoizzo PIM), my container get corrupted on the target hardware node because it is full of broken symlinks.

From what I understand, this is due to cached files not being replicated on the target hardware node. I beleive openvz should handle migrating dependant template files automagically, but obviously this is not the case.

Does anyone know what actions / commands should be used to prevent such a problem from occuring and migrate properly a container ?

Thanks for your time,

Alban
