I know that this works on a regular kernel.

I did not set up this OpenVZ host machine, I'm using a container id and need to set it up to route packets to both subnets.

But unless, from my limited understanding of OpenVZ (this is only my second time using it), how can I even setup a container for this purpose on virtual interfaces when from the actual server machine shell I'm unable to ping hosts on the 172 subnet through the eth1 interface?

Aren't physical eth0 and eth1 interfaces (in my case) supposed to be setup properly before the containers can use them?

Thank you for your replies so far, however, this has everything to do with OpenVZ.
