The uname script only works for things that actually call /bin/uname. At the moment, I've replaced /bin/bash with a slightly modified setarch that setarch's then runs the real bash. Is there a bug open or version-eta for the vzctl setarch feature?

Something interesting...

If I do:

```
setarch i686 vzctl start 200
```

then SSH into the VPS and do `uname -ar`, it will say `i686`. If I do `vzctl enter 200`, it'll say `x86_64`.

So for now, a "cleaner" solution seems to be doing setarch to vzctl.
