Ok, that one solved the mystery:

/dev/dm-10 is a luks-encrypted disk, which has been shut off due to power-supply failure, and since that one was not hot-swap, it still shows up as an active block device.

Didn't think of that, because that disk was not used for anything, and which is why I have no clue, why vmdump tries to access that drive.

Thanks, sHaggY\_caT.
