Hi Jim,

Thanks for the help that you have offered until now. It is really great.

let me clear the situation: I have a DSL modem which is the gateway to the external world.

```
vzctl set 101 --nameserver <IP-OF-DSL-Modem> --save
```

This solves the problem and 101 is able to ping google.com.

However, I have another system (centos on centos) which was not installed by me, where the VE has, as nameserver, the IP of its host and still it is able to ping domains. So this has to do with iptables I guess, I am not sure.

But anyway, now I have a connection for the VE and I was able to update it and populate it with firefox, apache2, php, mysql, etc. The next step is to re-package a new template. It is a nice experience until now. Any more advice for such a Web server? Performance/security tuning? Still I need help to fix my iptables thing.

Thanks again,

Blaise
