Hello all.

I run a small hosting company specializing in reseller accounts.

I have my primary website <http://www.siterack.net> located on a separate physical VPS, away from my primary hosting servers.

Due to changes in the economy I am looking for ways to cut operating costs. I would place my main on the main server, but if someone's IP gets blocked, that means they cannot login to my site to get live chat.

Long story short, I would like an effective way to place my site on my primary dedicated server, and drop the VPS I have, while keeping my site separated from the SPI firewall.

Can I install OpenVZ on an operational server that was not originally configured as a VPS node?

If not, does anyone know how I could place my site on my primary server and create a passthrough for my domain on CSF firewall?

Any info is appreciated, thanks

Chris Walker
