Ok, we are talking about the same things. We do it only in a different way:

* separate routing table :

```
namespace
|
\--- route_tables
|
\---routes
```

* tagged routing table :

```
route_tables
|
\---routes
|
\---namespace
```

When using routes private to the namespace, globally the logic of the ip stack is not changed, it manipulates only different variables. It is more clean than tagging the route for the reasons mentioned by Eric.

When using route tagging, the logic is changed because when doing lookup on the routes table which is global, the namespace is used to match the route and make it visible.

I use the second method, because I think it is more efficient and reduce the overhead. But the isolation is minimalist and only aims to avoid the application using resources outside of the container (aka namespace) without taking care of the system. For example, I didn't take care of network devices, because as far as see I can't imagine an administrator wanting to change the network device name while there are hundred of containers running. Concerning tunnel devices for example, they should

be created inside the container.

I think, private network resources method is more elegant and involves more network resources, but there is probably a significant overhead and some difficulties to have __lightweight__ container (aka application container), make nfs working well, etc... I did some tests with tbench and the loopback with the private namespace and there is roughly an overhead of 4 % without the isolation since with the tagging method there is 1 % with the isolation.

The network namespace aims the isolation for now, but the container based on the namespaces will probably need checkpoint/restart and migration ability. The migration is needed not only for servers but for HPC jobs too.

So I don't know what level of isolation/virtualization is really needed by users, what should be acceptable (strong isolation and overhead / weak isolation and efficiency). I don't know if people wanting strong isolation will not prefer Xen (clearly with much more overhead than your patches ;))
