Linux 2.6.26-2-openvz-amd64

it is possible to set a core_pattern starting with a | in order to have your core file processed by a program before being generated.  On the parent system (server01), i set the core pattern, and i'm able to generate core dumps that get processed.  on the virtual system (server02) it seems to take the core pattern from the parent., but whenever something would generate a core, it doesn't, and the dmesg on the parent server says

[469586.116037] Core dump to |/filename pipe failed

in case it was using the path to the file on the virtual server, i placed a copy of the file on both the virtual and physical machines.

do virtual servers handle pipes in the core pattern file?  or am i doing something wrong?
