Yes, that would be it. You're going to need to run ovzkernel and have ovzkernel-headers, compilers and OpenAFS dependencies (probably various -devel packages) installed. You'll be able to see most of the dependencies listed in the OpenAFS .spec file.

As you already have a good SRPM, it might be as simple as 'rpmbuild -ba xxx.spec'.

I'd advise you to look at CentOS or Fedora RPM building how-to's (or Scientific Linux, if it has them). The entire process is documented very well and is a lot easier than it might seem. Just be sure to set up the RPM building environment properly and don't try to build the RPM on a production server as root.

Good luck.
