I have a few questions about all the network isolation stuff:

* What level of isolation is wanted for the network ? network devices
? IPv4/IPv6 ? TCP/UDP ?

* How is handled the incoming packets from the network ? I mean what
will be mechanism to dispatch the packet to the right virtual device ?

* How to handle the SO_BINDTODEVICE socket option ?

* Has the virtual device a different MAC address ? How to manage it
with the real MAC address on the system ? How to manage ARP, ICMP,
multicasting and IP ?

It seems for me, IMHO that will require a lot of translation and
browsing table. It will probably add a very significant overhead.

* How to handle NFS access mounted outside of the container ?

* How to handle ICMP_REDIRECT ?

Regards
