Agreed.

Why do we need to account for swap IO? Application never asked for swap IO. It is kernel's decision to move some pages to swap to free up some memory. What's the point in charging those pages to application group and throttle accordingly?

Yes page tracking will be needed for CFQ proportional bandwidth ASYNC write support. But until and unless we implement memory cgroup dirty ratio and figure a way out to make writeback logic cgroup aware, till then I think page tracking stuff is not really useful.

Cool, I would like to play with it a bit once patches are ready.

Thanks  
Vivek
