Subject: Server won't reboot after install

Hello.

I've installed OpenVZ a number of times and I've never had a problem until now. I'm leasing an AMD Phenom II 1055T server and installing OVZ is being a major pain.

I follow the instructions in the OVZ wiki (the Quick Install Guide) to the letter (using yum rather than rpm) and then when I reboot, nothing. I can't tell what's wrong because my only option is to have the server wiped so I can start again. Obviously this can only occur so many times.

Does anyone have any idea what might be happening?

I'm using CentOS 5.6 64 bit and it's a fresh install (once with a yum update but I tried once without).

Thanks to anyone who has had this issue before!
