---

We have a few VPS with the same issues. They are located on the same node and they communicate but the problem is the bandwidth is actually being counted by our data center. For example we have one vps for a webserver the other as a mysql and over 500GB of data is being counted as actual bandwidth even though its just communication between the 2.

Is there someway we can configure them to communicate on private ips so the traffic isn't going through the switch?
