Yes, that is how I see it too. When I went to them with this issue, they admitted that they don't really know OpenVZ but said this:

"From what I have been able to find it is related to the venet virtual MAC addresses. The pool it may be making them up from might be conflicting with other client's OpenVZ virtual MACs as well. That is just a guess, I am not an OpenVZ expert."

I wanted to get back to them with some information to help them manage their ARP cache better so it doesn't happen again. However it might have been something I did, so I'm not entirely sure what (or if) anything needs to be done here.

Myles
