

I know this is has probably been discussed ad nauseum, but I haven't found what I'm looking for yet, so I thought I would ask here.

I have been running OpenVZ for a few years, but in the last couple of weeks, I have noticed over the past couple of weeks that several VMs were getting out of spec settings, mainly dcachesize growing too large.

These VMs started on a Debian openvz box, and as my virtual infrastructure grew, I started using a pair of proxmox-ve machines (which is Debian-lenny based as well), which are clustered.

I have 8 VMs that were created over time, some on 32-bit host machines, some on 64-bit. Thus, some have /proc/user_beancounters that look like:

1:	kmemsize	13775736		
15028224	48811846	51254098		63446
	lockedpages	0

I have three questions. First, I know that leaving everything unlimited is a quick path to running out of resources on the host machine. That said, I've been having troubles recently with the VMs with "normal" settings. It started out with dcachesize going out of spec, which, when I adjusted it, within an hour, I started getting out of memory errors, requiring me to up the kmemsize...This then caused problems on another "normal" VM, and so forth.

As I said, I know setting everything to unlimited is probably not recommended, so what is the recommended way to set the proper values for user_beancounters? Every time I change values in user_beancounters, something else comes unglued, except for the ones that have unlimited kmemsize and dcachesize.

Is there a tool to set up the values based on the use of the particular VM?
Is there any more information I need to provide?

Thanks,
--b
