I am a total noobie at openvz.

My current system is debian squeeze, and I followed the standard install guide from openvz.org's install wiki.   My server's network configuration is standard debian for adding multiple ip addresses... eth0, eth0:1, etc....   This is a fresh debian install with only openvz and its packages installed.

My problem is that when I create a new VM from any template. the VM is not able to connect out to my LAN or web.

I am not sure where this problem might lay. I have checked the VM's network configuration and they are showing my netmask, gateway, and broadcast #s as totally incorrect.

I am pretty lost here. I have done enough reading to see this is a common problem, but there has never been a solution posted before.
