Thanks for the info, much appreciated!

Maybe a little off topic, but I am curious to know: At the moment I find it very convenient to go directly into a containers filesystem from the hardware node - i.e. something like /vz/private/xxx/var/log/... etc -  
Would I be correct in presuming that by using ploop this will no longer be possible? I know I could just setup a test system and try it out but if you know already it would save me some time ;)

Indeed, this is the only container on that filesystem and that physical drive. This time there were no "spill over" but previous times when load hit 50 or more the load certainly did spill into other containers.

Best,  
Rene
