I have a bunch of containers on centos 6. when I map one to the nfs share and have a webserver use the nfs share to store the page data it absolutely bogs the host laverage went to 19. If i load a webserver on the host it snaps right through the pages as I would expect it to load. the nfs server and containers are both in the smae esxi server. the nfs has its own switch/nic/network. the ct has a 2nd ip and iptables masqrade through the 2nd nic for the nfs.

any thoughts would be appriciated. laverage on every thing when not using the ct/nfs is .7 for the nfs server and centos. copying data wholesale eats up cpu but thats not exactly suprising
