Others calls in the driver to shost_for_each_device unlock the host_lock while in the loop, makes sense to do the same in that loop as well given that these actions are taken when the adapter is quiesced. I worry, though, completion of the commands with QUEUE_FULL may result in them being turned around immediately which could clutter up the list. Could you experiment with this change:

```
static void adpt_fail_posted_scbs(adpt_hba* pHba)
{
    struct scsi_cmnd*   cmd = NULL;
    struct scsi_device* d;

    #if (LINUX_VERSION_CODE >= KERNEL_VERSION(2,5,65))
    # if ((LINUX_VERSION_CODE > KERNEL_VERSION(2,6,0)) ||
defined(shost_for_each_device))
+    spin_unlock(pHba->host->host_lock);
    shost_for_each_device(d, pHba->host) {
    # else
        list_for_each_entry(d, &pHba->host->my_devices, siblings) {
    # endif
            unsigned long flags;
            spin_lock_irqsave(&d->list_lock, flags);
            list_for_each_entry(cmd, &d->cmd_list, list) {
                if (cmd->serial_number == 0) {
                    continue;
                }
                cmd->result = (DID_OK << 16) | (QUEUE_FULL <<
1);
                cmd->scsi_done(cmd);
            }
            spin_unlock_irqrestore(&d->list_lock, flags);
        }
    }
    +# if ((LINUX_VERSION_CODE > KERNEL_VERSION(2,6,0)) ||
defined(shost_for_each_device))
+    spin_lock(pHba->host->host_lock);
    +# endif
    #else
        d = pHba->host->host_queue;
```

Sincerely -- Mark Salyzyn
