I did not find an answer on this question on google and also want to know how this is possible.

For now I did the following trick:

While running the VM with ploop, copied root/vpsid elsewhere.
Make sure you stop all services on the VM. Then destroyed the VM and created a new one with simfs, copied back the data and VM started. All works fine.

Our VirtualManager control panel does not work with ploop VPS's. And did not know that suddenly openvz defaults to the ploop layout. I had to modify the vz.conf.

And I do not like ploop at all

Regards,
Danny.
