Hello, the cpulimit resource does a fine job, but lets say a vps has 20 programs trying to run at once. They will use all of the cpulimit and beause they take longer to complete, the number of average running procs will be much higher than normal, which causes the hardware server's load to be higher.

So, it seems to me that cpulimit can hurt overal system performance under certain circumstances (more than a few concurrent, long-running processes per ve).

Is it possible to somehow limit the number of running procs in a ve? Am I missing something, like a simple workaround the problem stated above.

Thank you  
Harold
