hello,

I'm new to openvz, I have installed this fresh 7.0 release from iso on a hardware host and while setting up networking I discovered that some docs are outdated.

[https://wiki.openvz.org/Using\\_private\\_IPs\\_for\\_Hardware\\_Nodes](https://wiki.openvz.org/Using_private_IPs_for_Hardware_Nodes)  
this works unless you try to persist settings. instructions rely on vznetcfg and its supplementary files which seem to be gone and unsupported in 7.0. I have discovered that all bridge-related settings should be instead applied with prlctl since set --netif\_add now accepts --ipadd and related settings documented at [https://docs.openvz.org/openvz\\_command\\_line\\_reference.webhel p/\\_network\\_options.html](https://docs.openvz.org/openvz_command_line_reference.webhel p/_network_options.html)

I think the same applies to [https://openvz.org/Virtual\\_Ethernet\\_device#Making\\_a\\_veth-dev\\_ice\\_persistent](https://openvz.org/Virtual_Ethernet_device#Making_a_veth-dev_ice_persistent) - you should change the docs or clarify which openvz versions those advices apply to

The command line reference page  
[https://docs.openvz.org/openvz\\_command\\_line\\_reference.webhel p/\\_network\\_options.html](https://docs.openvz.org/openvz_command_line_reference.webhel p/_network_options.html) itself contains an error (or is this a prlctl bug??). Adding --host\_ifname to command line triggers error Unrecognized option: --host\_ifname - is there a mistype is option name maybe? Didn't figure this out yet
