Thank you for support.

My case is:

There is share directory on the host. This share is mount in several container through simfs. I need the total quota for the share. For this I using the own mount script ("vzquota on" is for first mount of share directory into the container and "vzquouta off" is for last unmount share directory, for example in case "service vz stop"). But sometimes (in case reboot host with share directory as bash working directory for example) the qouta is not disable correctly. Thus the containers start very long. All containers are waiting the recalculating of share directory (there are a lot of files). I want to disable the recalculating in my mount script. Inaccuracy in the calculation for me is not critical. I thought "quota on -f" disable the recalculating.
