We leave here the solution for those who can use it:

We access the physical machine and download the following package:

http://vault.centos.org/7.2.1511/os/x86_64/Packages/iproute-3.10.0-54.el7.x86_64.rpm

When it is unloaded we move it to the container where we have the problem.

Now, we enter the container and navigate to where we left the rpm file.

Now we run `yum downgrade iproute-3.10.0-54.el7.x86_64.rpm`

And `systemctl restart network`

NOTE: I know it is not the right forum but I have the same problem in some machines with Proxmox 3.4 and they do not even allow access so this solution is not valid.
Any solution to make the exchange of rpm files inside the virtual machine?
