Yep definitely seeing this issue here too. Had to convert a bunch of stuff to ipset to help lighten the overhead that this issue inevitably creates. Someone had commented in the official bug report that they didn't think this would be fixed until OpenVZ 8, but that seems pretty unlikely to me given that iptables management is handled by the OpenVZ kernel (ie: they have full access to deal with that) and even if the changes need to occur within the CentOS 8 container, that could be adjusted via the ez template.

Then again, devs have indeed taken their time with this...
