Hey, thanks for replying!

I've tried that exact command, it's no different from running pcompact as far as I can tell. I've tried running it directly on the root.hdd snapshot files as well, and it does nothing. With the snapshots in place, the disk is "locked" into the base root.hdd file. Only if I delete all of the snapshots first can I free up the wasted disk space in the root.hdd file by running pcompact.

They are live snapshots, and to be honest I haven't tested with offline snapshots. Maybe worth a shot, but we have so many live containers we can't have downtime on them even overnight it would be sloppy.
