Just wondering...

is it possible to mount different filesystems into one VE?

The simple approach of mounting filesystems into the VE private directory doesn't seem to work.

I configured two raids (as two LVM VGs) on my server, using different sets of disks to distribute IO load, e.g. having a mysql daemon working on one raid and storing maildirs on the other one.

Maybe such a configuration is just not the "OpenVZ way" and I should configure different VEs on different volumes for different jobs.

What surprised me is that I found no documentation concerning multiple filesystems in one VE. I guess it would be possible to export LVM devices to the VE, creating the corresponding device files in there and mounting them from inside the VE?

But would it then be possible to access the files from the host system?

I'm just curious ;)
