I didn't change anything with the memory reporting, and it still works on my end. Though that doesn't mean much.

I'm wondering how the user_beancounters file works with multi-core processors. It's quite possible that it does not present the same viewpoint that the cpuinfo file does. Calculating through cpuinfo simply adds up the value of the individual cores (processors * cores per processor * cpu speed). That part I'm comfortable is correct. The part I don't know is whether or not user_beancounters displays with the same point of reference.

I suppose that would be a question, though, for the OpenVZ developers (or for myself by digging through the OpenVZ code).
