Hi,

I am a newbie. So, kindly bear with me if this sounds silly. I have created 4 virtual servers (all running centos) on a main hardware node (which has got centos). I am using 1GB RAM. Recently I found a strange anamoly in the RAM space utilization. After I booted the main hardware node I did a "free -m" and found this:

	total	used	free	shared	buffers	cached
Mem:	942	535	406	0	106	209
-/+ buffers/cache:		219	723			
Swap:	1919	0	1919			

After some time (approx half an hour), inspite of no activity taking place on the machine, I found the following by using the free -m command:

	total	used	free	shared	buffers	cached
Mem:	942	536	406	0	106	209
-/+ buffers/cache:		219	723			
Swap:	1919	0	1919			

I tried it again after an hour, and again I found the memory utilization increasing.

	total	used	free	shared	buffers	cached
Mem:	942	537	405	0	107	210
-/+ buffers/cache:		219	723			
Swap:	1919	0	1919			

It keeps increasing this way, although the system is idle.

I have read few articles suggested in the forum (FAQ) like the foll:

[http://gentoo-wiki.com/FAQ\\_Linux\\_Memory\\_Management](http://gentoo-wiki.com/FAQ_Linux_Memory_Management)

But, I really doubt if this is the case because the cache and buffer size are the same and only the amount of memory getting utilized is increasing.

The only thing that is puzzling me is this that, if there is no activity taking place on my system, how come the memory utilized is increasing???

Can anyone help me in this regard????Thanks in advance!!!

[Moderator: added CODE tags to read free output more easy]
