Subject: Variable Configuration
Posted by virtualhome on Thu, 07 Dec 2006 03:01:27 GMT

Working within an OpenVZ environment, how can I bring up different kinds of configurations on the same box.

For example, running RedHat with OpenVZ, I need to simulate OS#1 to run App#1 and App#2. Then OS#2 runs App#3 thur App#6. And then OS#3 will run App#7. Do I need to install all seven apps on the OS and turn each on as I bring up each OS?

And then I need to simulate failover with OS#3 and OS#4 each running App#7. Or I want to run different configuration files in the mix. How to I bring up a given simulation environment for a particular testing environment?

So, can how does OpenVZ do this?
