Hi,

I've been having to reboot my server (hardware node) a number of times lately due to some stability issues as well as updates etc. Whenever there has been a hardware node crash the vzquotas keep needing to be recalculated each time before the containers will start again (after reboot/power cycling). With a large VPS it can take over an hour to run the vzquota calculation. Is there any possibility that a vzquota calculation could be done after a VPS has already started running? In other words could the VPS be started immediately and then the vzquota calculation run in the background, meaning less downtime. This would greatly help us and I'm sure many others who experience a random crash from time to time.

Sounds like a good idea to me, but I think you need to add it to the bugzilla system for anyone to take notice...
