Hi,

We run a collection of 8 x CentOS 5 OpenVZ hardware nodes in a UK data center.

Each hardware node is on a private internal network that is connected to a firewall server running vanilla CentOS 5.

Everything seems to be working fine, except for 1 thing.

We run a service that runs regular whois lookups on IPs, however we have discovered that some of the containers cannot connect to whois.ripe.net on TCP port 43 (even using telnet it cannot connect).

Interestingly, the problem seems to be intermittent, and when we reboot the hardware node it becomes possible to telnet to that host again, but as soon as we try it from a container running on that hardware node it timesout and causes the hardware node to timeout too.

This seems to happen on 4 out of the 8 hardware nodes, and there seems to be no pattern between kernel version or useland versions.

Has anyone seen anything like this before!?

Thanks

I'm running centos6 on HN
and centos5 in CT

I had same issue, but what interesting it works with domains, but not with ip addresses

I mean
whois google.It works
whois some_ip does not

just today I have found that when I do whois some_ip it tries to access some ipv6 ip address.

if in CT I disable ipv6 networking it works
so, in CT file /etc/sysconfig/network

```
set
NETWORKING_IPV6="no"
```

```
restart network in CT:
/etc/init.d/network restart
```

and it should work

OK, thanks for that, I will try and give it a go.

Hi,

I have tried that approach and it has not helped the issue.

Interestingly it seems to be caused by upgrading the machines to the later versions of the OpenVZ kernel.

I cannot even telnet to the RIPE IP 193.0.6.135 on port 43.
