Subject: [PATCH 00/23] slab+slub accounting for memcg
Posted by Glauber Costa on Fri, 20 Apr 2012 21:57:08 GMT
View Forum Message <> Reply to Message

Hi,

This is my current attempt at getting the kmem controller
into a mergeable state. IMHO, all the important bits are there, and it should't
change *that* much from now on. I am, however, expecting at least a couple more
interactions before we sort all the edges out.

This series works for both the slub and the slab. One of my main goals was to
make sure that the interfaces we are creating actually makes sense for both
allocators.

I did some adaptations to the slab-specific patches, but the bulk of it
comes from Suleiman's patches. I did the best to use his patches
as-is where possible so to keep authorship information. When not possible,
I tried to be fair and quote it in the commit message.

In this series, all existing caches are created per-memcg after its first hit.
The main reason is, during discussions in the memory summit we came into
agreement that the fragmentation problems that could arise from creating all
of them are mitigated by the typically small quantity of caches in the system
(order of a few megabytes total for sparsely used caches).
The lazy creation from Suleiman is kept, although a bit modified. For instance,
I now use a locked scheme instead of cmpxcgh to make sure cache creation won't
fail due to duplicates, which simplifies things by quite a bit.

The slub is a bit more complex than what I came up with in my slub-only
series. The reason is we did not need to use the cache-selection logic
in the allocator itself - it was done by the cache users. But since now
we are lazy creating all caches, this is simply no longer doable.

I am leaving destruction of caches out of the series, although most
of the infrastructure for that is here, since we did it in earlier
series. This is basically because right now Kame is reworking it for
user memcg, and I like the new proposed behavior a lot more. We all seemed
to have agreed that reclaim is an interesting problem by itself, and
is not included in this already too complicated series. Please note
that this is still marked as experimental, so we have so room. A proper
shrinker implementation is a hard requirement to take the kmem controller
out of the experimental state.

I am also not including documentation, but it should only be a matter
of merging what we already wrote in earlier series plus some additions.

Glauber Costa (19):

slub: don't create a copy of the name string in kmem_cache_create
slub: always get the cache from its page in kfree
slab: rename gfpflags to allocflags
slab: use obj_size field of struct kmem_cache when not debugging
change defines to an enum
don't force return value checking in res_counter_charge_nofail
kmem slab accounting basic infrastructure
slab/slub: struct memcg_params
slub: consider a memcg parameter in kmem_create_cache
slab: pass memcg parameter to kmem_cache_create
slub: create duplicate cache
slub: provide kmalloc_no_account
slab: create duplicate cache
slab: provide kmalloc_no_account
kmem controller charge/uncharge infrastructure
slub: charge allocation to a memcg
slab: per-memcg accounting of slab caches
memcg: disable kmem code when not in use.
slub: create slabinfo file for memcg

Suleiman Souhlal (4):
memcg: Make it possible to use the stock for more than one page.
memcg: Reclaim when more than one page needed.
memcg: Track all the memcg children of a kmem_cache.
memcg: Per-memcg memory.kmem.slabinfo file.

Subject: [PATCH 01/23] slub: don't create a copy of the name string in kmem_cache_create
Posted by Glauber Costa on Fri, 20 Apr 2012 21:57:09 GMT
View Forum Message <> Reply to Message

When creating a cache, slub keeps a copy of the cache name through
strdup. The slab however, doesn't do that. This means that everyone

registering caches have to keep a copy themselves anyway, since code
needs to work on all allocators.

Having slab create a copy of it as well may very well be the right
thing to do: but at this point, the callers are already there

My motivation for it comes from the kmem slab cache controller for
memcg. Because we create duplicate caches, having a more consistent
behavior here really helps.

I am sending the patch, however, more to probe on your opinion about
it. If you guys agree, but don't want to merge it - since it is not
fixing anything, nor improving any situation etc, I am more than happy
to carry it in my series until it gets merged (fingers crossed).

```
A consistent name with slub saves us an acessor function.
In both caches, this field represents the same thing. We would
like to use it from the mem_cgroup code.

Subject: [PATCH 05/23] memcg: Reclaim when more than one page needed.
Posted by Glauber Costa on Fri, 20 Apr 2012 21:57:13 GMT
View Forum Message <> Reply to Message

From: Suleiman Souhlal <ssouhlal@FreeBSD.org>

mem_cgroup_do_charge() was written before slab accounting, and expects
three cases: being called for 1 page, being called for a stock of 32 pages,
or being called for a hugepage. If we call for 2 pages (and several slabs
used in process creation are such, at least with the debug options I had),
it assumed it's being called for stock and just retried without reclaiming.

Fix that by passing down a minsize argument in addition to the csize.

And what to do about that (csize == PAGE_SIZE && ret) retry? If it's
needed at all (and presumably is since it's there, perhaps to handle
races), then it should be extended to more than PAGE_SIZE, yet how far?
And should there be a retry count limit, of what? For now retry up to
COSTLY_ORDER (as page_alloc.c does), stay safe with a cond_resched(),
and make sure not to do it if __GFP_NORETRY.

Subject: [PATCH 06/23] slab: use obj_size field of struct kmem_cache when not debugging
Posted by Glauber Costa on Fri, 20 Apr 2012 21:57:14 GMT
View Forum Message <> Reply to Message

The kmem controller needs to keep track of the object size of
a cache so it can later on create a per-memcg duplicate. Logic
to keep track of that already exists, but it is only enable while
debugging.

This patch makes it also available when the kmem controller code
is compiled in.

Since we will succeed with the allocation no matter what, there
isn't the need to use __must_check with it. It can very well
be optional.

Subject: [PATCH 09/23] kmem slab accounting basic infrastructure
Posted by Glauber Costa on Fri, 20 Apr 2012 21:57:17 GMT
View Forum Message <> Reply to Message

This patch adds the basic infrastructure for the accounting of the slab caches. To control that, the following files are created:

 * memory.kmem.usage_in_bytes
 * memory.kmem.limit_in_bytes
 * memory.kmem.failcnt
 * memory.kmem.max_usage_in_bytes

They have the same meaning of their user memory counterparts. They reflect the state of the "kmem" res_counter.

The code is not enabled until a limit is set. This can be tested by the flag "kmem_accounted". This means that after the patch is applied, no behavioral changes exists for whoever is still using memcg to control their memory usage.

We always account to both user and kernel resource_counters. This effectively means that an independent kernel limit is in place when the limit is set to a lower value than the user memory. A equal or higher value means that the user limit will always hit first, meaning that kmem is effectively unlimited.

People who want to track kernel memory but not limit it, can set this limit to a very high number (like RESOURCE_MAX - 1page - that no one will ever hit, or equal to the user memory)

Subject: [PATCH 10/23] slab/slub: struct memcg_params
Posted by Glauber Costa on Fri, 20 Apr 2012 21:57:18 GMT

For the kmem slab controller, we need to record some extra
information in the kmem_cache structure.

Subject: [PATCH 11/23] slub: consider a memcg parameter in kmem_create_cache
Posted by Glauber Costa on Fri, 20 Apr 2012 21:57:19 GMT
View Forum Message <> Reply to Message

Allow a memcg parameter to be passed during cache creation.
The slub allocator will only merge caches that belong to
the same memcg.

Default function is created as a wrapper, passing NULL
to the memcg version. We only merge caches that belong
to the same memcg.

>From the memcontrol.c side, 3 helper functions are created:

 1) memcg_css_id: because slub needs a unique cache name
    for sysfs. Since this is visible, but not the canonical
    location for slab data, the cache name is not used, the
    css_id should suffice.

 2) mem_cgroup_register_cache: is responsible for assigning

a unique index to each cache, and other general purpose
setup. The index is only assigned for the root caches. All
others are assigned index == -1.

3) mem_cgroup_release_cache: can be called from the root cache
destruction, and will release the index for other caches.

This index mechanism was developed by Suleiman Souhlal.

Subject: [PATCH 12/23] slab: pass memcg parameter to kmem_cache_create
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:29 GMT
View Forum Message <> Reply to Message

Allow a memcg parameter to be passed during cache creation.

Default function is created as a wrapper, passing NULL
to the memcg version. We only merge caches that belong
to the same memcg.

This code was mostly written by Suleiman Souhlal and
only adapted to my patchset, plus a couple of simplifications

Subject: [PATCH 13/23] slub: create duplicate cache
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:30 GMT
View Forum Message <> Reply to Message

This patch provides kmem_cache_dup(), that duplicates
a cache for a memcg, preserving its creation properties.
Object size, alignment and flags are all respected.

When a duplicate cache is created, the parent cache cannot
be destructed during the child lifetime. To assure this,
its reference count is increased if the cache creation
succeeds.

Subject: [PATCH 14/23] slub: provide kmalloc_no_account
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:31 GMT
View Forum Message <> Reply to Message

Some allocations need to be accounted to the root memcg regardless
of their context. One trivial example, is the allocations we do
during the memcg slab cache creation themselves. Strictly speaking,
they could go to the parent, but it is way easier to bill them to
the root cgroup.

Only generic kmalloc allocations are allowed to be bypassed.

The function is not exported, because drivers code should always
be accounted.

Subject: [PATCH 15/23] slab: create duplicate cache
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:32 GMT
View Forum Message <> Reply to Message

This patch provides kmem_cache_dup(), that duplicates
a cache for a memcg, preserving its creation properties.
Object size, alignment and flags are all respected.
An exception is the SLAB_PANIC flag, since cache creation
inside a memcg should not be fatal.

This code is mostly written by Suleiman Souhlal,
with some adaptations and simplifications by me.

Subject: [PATCH 17/23] kmem controller charge/uncharge infrastructure
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:34 GMT
View Forum Message <> Reply to Message

With all the dependencies already in place, this patch introduces
the charge/uncharge functions for the slab cache accounting in memcg.

Before we can charge a cache, we need to select the right cache.
This is done by using the function __mem_cgroup_get_kmem_cache().

If we should use the root kmem cache, this function tries to detect
that and return as early as possible.

The charge and uncharge functions comes in two flavours:
 * __mem_cgroup_(un)charge_slab(), that assumes the allocation is
   a slab page, and
 * __mem_cgroup_(un)charge_kmem(), that does not. This later exists
   because the slub allocator draws the larger kmalloc allocations
   from the page allocator.

In memcontrol.h those functions are wrapped in inline acessors.
The idea is to later on, patch those with jump labels, so we don't
incur any overhead when no mem cgroups are being used.

Because the slub allocator tends to inline the allocations whenever
it can, those functions need to be exported so modules can make use
of it properly.

I apologize in advance to the reviewers. This patch is quite big, but
I was not able to split it any further due to all the dependencies
between the code.

This code is inspired by the code written by Suleiman Souhlal,
but heavily changed.

Subject: [PATCH 18/23] slub: charge allocation to a memcg
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:35 GMT
View Forum Message <> Reply to Message

This patch charges allocation of a slab object to a particular
memcg.

The cache is selected with mem_cgroup_get_kmem_cache(),
which is the biggest overhead we pay here, because
it happens at all allocations. However, other than forcing
a function call, this function is not very expensive, and
try to return as soon as we realize we are not a memcg cache.

The charge/uncharge functions are heavier, but are only called
for new page allocations.

The kmalloc_no_account variant is patched so the base
function is used and we don't even try to do cache
selection.

Subject: [PATCH 19/23] slab: per-memcg accounting of slab caches
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:36 GMT
View Forum Message <> Reply to Message

This patch charges allocation of a slab object to a particular

memcg.

The cache is selected with mem_cgroup_get_kmem_cache(),
which is the biggest overhead we pay here, because
it happens at all allocations. However, other than forcing
a function call, this function is not very expensive, and
try to return as soon as we realize we are not a memcg cache.

The charge/uncharge functions are heavier, but are only called
for new page allocations.

Code is heavily inspired by Suleiman's, with adaptations to
the patchset and minor simplifications by me.

Subject: [PATCH 20/23] memcg: disable kmem code when not in use.
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:37 GMT
View Forum Message <> Reply to Message

We can use jump labels to patch the code in or out
when not used.

Because the assignment: memcg->kmem_accounted = true
is done after the jump labels increment, we guarantee
that the root memcg will always be selected until
all call sites are patched (see mem_cgroup_kmem_enabled).
This guarantees that no mischarges are applied.

Jump label decrement happens when the last reference
count from the memcg dies. This will only happen when
the caches are all dead.

Subject: [PATCH 21/23] memcg: Track all the memcg children of a kmem_cache.
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:38 GMT
View Forum Message <> Reply to Message

From: Suleiman Souhlal <ssouhlal@FreeBSD.org>

This enables us to remove all the children of a kmem_cache being
destroyed, if for example the kernel module it's being used in
gets unloaded. Otherwise, the children will still point to the
destroyed parent.

We also use this to propagate /proc/slabinfo settings to all
the children of a cache, when, for example, changing its
batchsize.

Subject: [PATCH 22/23] memcg: Per-memcg memory.kmem.slabinfo file.
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:39 GMT
View Forum Message <> Reply to Message

From: Suleiman Souhlal <ssouhlal@FreeBSD.org>

This file shows all the kmem_caches used by a memcg.

Signed-off-by: Suleiman Souhlal <suleiman@google.com>

Subject: [PATCH 23/23] slub: create slabinfo file for memcg
Posted by Glauber Costa on Sun, 22 Apr 2012 23:53:40 GMT
View Forum Message <> Reply to Message

This patch implements mem_cgroup_slabinfo() for the slub.
With that, we can also probe the used caches for it.

This seems horribly inconsistent with memcg charging of user memory since
it charges to p->mm->owner and you're charging to p. So a thread attached
to a memcg can charge user memory to one memcg while charging slab to
another memcg?

How do you handle when the memcg cgroup gets destroyed? Also that means only one memcg cgroup can be accounted for a given slab cache? What if that memcg cgroup has children? Hmm, perhaps this is handled in a further patch in the series, I saw a patch title with "children" inside :)

Also my knowledge on memory allocators is near zero, so I may well be asking weird questions...

```

I can't seem to find kmalloc_no_account() in this patch or may be
I missed it in a previous one?

Why this space for "dead" ? I can't seem to find a reference to that in
the kernel. Is it something I'm missing because of my lack of slab knowledge
or is it something needed in a further patch? In which case this should be
explained in the changelog.

Charging to the thread rather than the process seem to me the right behaviour:
you can have two threads of a same process attached to different cgroups.

Perhaps it is the user memory memcg that needs to be fixed?

Yes, because MEM_RES_CTLR_KMEM is dependent on RES_CTLR.

> How do you handle when the memcg cgroup gets destroyed?

I don't (yet), because - as mentioned in patch 0 - I decided to hold
those patches until I had a better idea about how would Kame's
pre_destroy() patches look like. I plan, however, to include it in the
next version.

The idea is basically to mark the caches as dead (answers another
question of yours), and wait until it runs out of objects. Talking
specifically about the slub, that happens when free_page() frees the
last page of the cache *and* its reference count goes down to zero
(kmem_cache_destroy() drops the refcnt, so it will mean that cgroup
destruction already called it)

When we have a shrinker - I don't plan to include a per-memcg shrinker
in the first merge, because let's face it, it is a hard problem in
itself that would be better thought separately - we can call the
shrinkers to force the objects to die earlier.

> Also that means only one
> memcg cgroup can be accounted for a given slab cache?

Not sure if I understand your question in an ambiguity-free way.
If you mean the situation in which two tasks touch the same object, then
yes, only one of them is accounted.

If you mean about types of cache, then no, each memcg can have it's own
version of the whole cache array.

> What if that memcg cgroup has
> children? Hmm, perhaps this is handled in a further patch in the series, I saw a
> patch title with "children" inside :)

then the children creates caches as well, as much as the parents.

Note that because of the delayed allocation mechanism, if the parent
serves only as a placeholder, and has no tasks inside it, then it will
never touch - and therefore never create - any cache.

It is in a previous one (actually two, one for the slab, one for the
slub). They are bundled in the cache creation, but I could separate it
for clarity, if you prefer.

>
> Why this space for "dead" ?

Ok, sorry. Since I didn't include the destruction part, it got too easy
for whoever wasn't following the last discussion on this to get lost -
My bad. So here it is:

When we destroy the memcg, some objects may still hold the cache in
memory. It is like a reference count, in a sense, which each object
being a reference.

In typical cases, like non-shrinkable caches that has create - destroy
patterns, the caches will go away as soon as the tasks using them.

But in cache-like structure like the dentry cache, the objects may hang
around until a shrinker pass takes them out. And even then, some of them
will live on.

In this case, we will display them with "dead" in the name.

We could hide them, but then it gets weirder because it would be hard to
understand where is your used memory when you need to inspect your system.

Creating another file, slabinfo_deadcaches, and keeping the names, is
also a possibility, if people think that the string append is way too ugly.

Hi David,

I just saw all the answers, so I will bundle here since Frederic also
chimed in...

I think memcg is not necessarily wrong. That is because threads in a
process share an address space, and you will eventually need to map a
page to deliver it to userspace. The mm struct points you to the owner
of that.

But that is not necessarily true for things that live in the kernel
address space.

Do you view this differently ?

No, because memory is represented by mm_struct, not task_struct, so you
must charge to p->mm->owner to allow for moving threads amongst memcgs
later for memory.move_charge_at_immigrate. You shouldn't be able to

charge two different memcgs for memory represented by a single mm.

Yes, for user memory, I see charging to p->mm->owner as allowing that
process to eventually move and be charged to a different memcg and there's
no way to do proper accounting if the charge is split amongst different
memcgs because of thread membership to a set of memcgs. This is
consistent with charges for shared memory being moved when a thread
mapping it moves to a new memcg, as well.

But that's the problem.

When we are dealing with kernel memory, we are allocating a whole slab
page. It is essentially impossible to track, given a page, which task
allocated which object.

Right, so you have to make the distinction that slab charges cannot be migrated by memory.move_charge_at_immigrate (and it's not even specified to do anything beyond user pages in Documentation/cgroups/memory.txt), but it would be consistent to charge the same memcg for a process's slab allocations as the process's user allocations.

My response was why we shouldn't be charging user pages to mem_cgroup_from_task(current) rather than mem_cgroup_from_task(current->mm->owner) which is what is currently implemented.

If that can't be changed so that we can still migrate user memory amongst memcgs for memory.move_charge_at_immigrate, then it seems consistent to have all allocations done by a task to be charged to the same memcg.
Hence, I suggested current->mm->owner for slab charging as well.

IIRC, it was for preventing rapid OOM kill and reducing latency.

No lock here ? you need find_first_zero_bit_and_set_atomic() or some.
Rather than that, I think you can use lib/idr.c::ida_simple_get().

```

There is a problem of OOM-Kill.
To free memory by killing process, 'mm' should be released by kill.
So, oom-killer just finds a leader of process.

Assume A process X consists of thread A, B and A is thread-group-leader.

Put thread A into cgroup/Gold
  thread B into cgroup/Silver.

If we do accounting based on threads, we can't do anything at OOM in cgroup/Silver.
An idea 'Killing thread-A to kill thread-B'..... breaks isolation.

As far as resources used by process, I think accounting should be done per process.
It's not tied to thread.

About kmem, if we count task_struct, page tables, etc...which can be freed by
OOM-Killer i.e. it's allocated for 'process', should be aware of OOM problem.
Using mm->owner makes sense to me until someone finds a great idea to handle
OOM situation rather than task killing.

Thanks,
-Kame

Not that I can think of. Well, actually, not without adding some tests
to the allocation path I'd rather not (like testing for the return
address and then doing a table lookup, etc)

An option would be to store it in the task_struct. So we would allocate
as following:

memcg_skip_account_start(p);
do_a_bunch_of_allocations();
memcg_skip_account_stop(p);

The problem with that, is that it is quite easy to abuse.
but if we don't export that to modules, it would be acceptable.

Question is, given the fact that the number of kmalloc_no_account() is
expected to be really small, is it worth it?

Quite arbitrary. Just large enough to hold all caches there are
currently in a system + modules. (Right now I have around 140
in a normal fedora installation)

This function is called from within kmem_cache_create(), that usually
already do locking. The slub, for instance, uses the slub_lock() for all
cache creation, and the slab do something quite similar. (All right, I
should have mentioned that in comments)

But as for idr, I don't think it is a bad idea. I will take a look.

this is inside ifndef (not defined), so this means anyone trying to pass
a memcg in that situation, is doing something really wrong.

I was actually going for BUG() on this one, but changed my mind

Thinking again, I could probably do this:

```
if (WARN_ON(memcg != NULL))
   memcg = NULL;
```

this way we can keep going without killing the kernel as well as
protecting the function.

We could.
But that is not the cache name, this is for alias files.

The cache name has css_id:dcache_name, so we'll see something like
2:container1

The css_id plays the role of avoiding name duplicates, since all we use
is the last dentry to derive the name.

So I guess if need arises to go search in sysfs for the slub stuff, it
gets easy enough to correlate so we don't need to export the id.

Why would it?

This one has more or less the same logic as the sock buffers.

If we are not accounted, the caches don't get created. If the caches
don't get created, we don't release them. (this is modulo bugs, of course)

Ah, all right. Well, for user memory I agree with you. My point was
exactly that user memory can always be pinpointed to a specific address
space, while kernel memory can't.

>
> If that can't be changed so that we can still migrate user memory amongst

All right. This can be done. Although I don't see this as a must for
slab as already explained, I certainly don't oppose doing so as well.

Okay. Please note how the logic works in description or Doc.
It's a bit complicated part.

Thanks,
-Kame

ok, but.... There was an idea __GFP_NOACCOUNT, which is better ?
Are you afraid that__GFP_NOACCOUNT can be spread too much rather than
kmalloc_no_account() ?

Thanks,
-Kame

They seem to be the 14th and 16th patches. They should probably
be before the current one for review clarity, so we define that function
before it gets used. This is also good to not break bisection.

Ok, thanks for the explanation.

The idea I had was more that only the memcg of the thread that does the allocation
is charged. But the problem is that this allocation can be later deallocated

from another thread. So probably charging the owner is indeed the only sane
way to go with user memory.

Right. But then if one wanted true isolation without worrying about such
side effect, he would avoid to scatter a thread group across more than one

memcg.

>
> As far as resources used by process, I think accounting should be done per process.
> It's not tied to thread.

Yep, makes sense. Especially as thread B might free memory allocated by thread A.
Maintaining a per thread granularity would create too much mess.

> About kmem, if we count task_struct, page tables, etc...which can be freed by
> OOM-Killer i.e. it's allocated for 'process', should be aware of OOM problem.

> OOM situation rather than task killing.

kmem is different because the memory allocated is in essence available to every
threads. Because this becomes a global resource, I don't find the accounting to p->mm->owner
more relevant than to p.

It's all really the same concept: if we want to move memory of a process,
willingly free memory in the process itself, or free memory of a process
by way of the oom killer, we need a way to do that for the entire process
so the accounting makes sense afterwards. And since we have that
requirement for user memory, it makes sense that its consistent with slab
as well. I don't think a thread of a process should be able to charge
slab to one memcg while its user memory is charged to another memcg.

Subject: [PATCH 0/3] A few fixes for '[PATCH 00/23] slab+slub accounting for memcg' series

The patches look great, thanks a lot for your work!

I finally tried them, and after a few fixes the kmem accounting
seems to work fine with slab. The fixes will follow this email,
and if they're fine, feel free to fold them into your patches.

However, with slub I'm getting kernel hangs and various traces[1].
It seems that kernel memcg recurses when trying to call
memcg_create_cache_enqueue() -- it calls kmalloc_no_account()
which was introduced to not recurse into memcg, but looking
into 'slub: provide kmalloc_no_account' patch, I don't see
any difference between _no_account and ordinary kmalloc. Hm.

OK, slub apart... the accounting works with slab, which is great.

There's another, more generic question: is there any particular
reason why you don't want to account slab memory for root cgroup?

Personally I'm interested in kmem accounting because I use
memcg for lowmemory notifications. I'm installing events
on the root's memory.usage_in_bytes, and the thresholds values
are calculated like this:

  total_ram - wanted_threshold

So, if we want to get a notification when there's 64 MB memory
left on a 256 MB machine, we'd install an event on the 194 MB
mark (the good thing about usage_in_bytes, is that it does
account file caches, so the formula is simple).

Obviously, without kmem accounting the formula can be very
imprecise when kernel (e.g. hw drivers) itself start using a
lot of memory. With root's slab accounting the problem
would be solved, but for some reason you deliberately do not
want to account it for root cgroup. I suspect that there are
some performance concerns?..

Thanks,

[1]

Subject: [PATCH 1/3] slab: Proper off-slabs handling when duplicating caches
Posted by Anton Vorontsov on Mon, 30 Apr 2012 10:01:21 GMT
View Forum Message <> Reply to Message

OFF_SLAB is not CREATE_MASK bit, so we should clear it before
calling __kmem_cache_create(), otherwise kernel gets very upset,
see below.

As a side effect, now we let slab to reevaluate off-slab
decision, but the decision will be the same, because whether
we do off-slabs only depend on the size and create_mask
bits.

Subject: [PATCH 2/3] slab: Fix imbalanced rcu locking
Posted by Anton Vorontsov on Mon, 30 Apr 2012 10:01:39 GMT
View Forum Message <> Reply to Message

Not sure why the code tries to unlock the rcu. The
only case where slab grabs the lock is around
mem_cgroup_get_kmem_cache() call, which won't result
into calling cache_grow() (that tries to unlock the rcu).

```
=====================================
[ BUG: bad unlock balance detected! ]
3.4.0-rc4+ #33 Not tainted

Subject: [PATCH 3/3] slab: Get rid of mem_cgroup_put_kmem_cache()
Posted by Anton Vorontsov on Mon, 30 Apr 2012 10:02:02 GMT
View Forum Message <> Reply to Message

The function is no longer used, so can be safely removed.

```

cache_cache probably doesn't get its id registered correctly. :-(
We might need to add a mem_cgroup_register_cache() call to kmem_cache_init().

```

Do we need rcu_dereference() here (and make sure we have rcu_read_lock())?

This might need to be done in all the other places in the patchset
that get the memcg's dentry.

> +               synchronize_rcu();
```

Is this synchronize_rcu() still needed, now that we don't use RCU to
protect memcgs from disappearing during allocation anymore?

Also, should we drop the memcg reference we got in
memcg_create_kmem_cache() here?

```

We might need rcu_dereference() here (and hold rcu_read_lock()).
Or we could just remove this message.

```
> +		/* Drop the reference gotten when we enqueued. */

```

Is it ok to call rcu_access_pointer() and rcu_dereference() without
holding rcu_read_lock()?

```

```

Why do we need to get a reference to the memcg for every charge?
How will this work when deleting a memcg?

```

```

Might need to uncharge memsw.

```

Don't we need to check in_interrupt(), current, __GFP_NOFAIL every time we call mem_cgroup_cgroup_get_kmem_cache()?

I would personally prefer if those checks were put inside mem_cgroup_get_kmem_cache() instead of having to check for every caller.

Because I am using the convention that setting it to any value different
than that will enable accounting.

```

For the slub, it seems to work okay. But I had to use the trick that for the memcg-specific kmalloc caches, they come from the normal caches rather than the special kmalloc pool. Since we are already paying the penalty of dealing with the memcg finding, I hope this is okay.

For the slab, my investigation wasn't that deep. But basic functionality works okay.

I have a reworked code I like better for this part.

It reads as follows:

```
static void kmem_cache_destroy_work_func(struct work_struct *w)
{
	struct kmem_cache *cachep;
	const char *name;
	struct mem_cgroup_cache_params *params, *tmp;
	unsigned long flags;
	LIST_HEAD(delete_unlocked);

	synchronize_rcu();

	spin_lock_irqsave(&cache_queue_lock, flags);
	list_for_each_entry_safe(params, tmp, &destroyed_caches,
destroyed_list) {
		cachep = container_of(params, struct kmem_cache,
memcg_params);
		list_move(&cachep->memcg_params.destroyed_list,
&delete_unlocked);
	}
	spin_unlock_irqrestore(&cache_queue_lock, flags);

	list_for_each_entry_safe(params, tmp, &delete_unlocked,
destroyed_list) {
		cachep = container_of(params, struct kmem_cache,
memcg_params);
		list_del(&cachep->memcg_params.destroyed_list);
		name = cachep->name;
		mem_cgroup_put(cachep->memcg_params.memcg);
		kmem_cache_destroy(cachep);
		kfree(name);
	}
}
```

I think having a list in stack is better because we don't need to hold &
drop the spinlock, and can achieve more parallelism if multiple cpus are

scheduling the destroy worker.

As you see, this version does a put() - so the answer to your question
is yes.

synchronize_rcu() also gets a new meaning, in the sense that it only
waits until everybody that is destroying a cache can have the chance to
get their stuff into the list.

But to be honest, one of the things we need to do for the next version,
is audit all the locking rules and write them down...

```

Don't understand this "or". Again, cache creation can still fail. This
is specially true in constrained memory situations.

```

No, but mem_cgroup_from_task should be called with rcu_read_lock() held
as well.

I forgot to change it in the comments, but this function should be
called with the rcu_read_lock() held. I was careful enough to check the
callers, and they do. But being only human, some of them might have
escaped...

```
>> +
>> +bool __mem_cgroup_charge_kmem(gfp_t gfp, size_t size)
>> +{
>> +       struct mem_cgroup *memcg;

>> +
>> +       mem_cgroup_get(memcg);
>
> Why do we need to get a reference to the memcg for every charge?
> How will this work when deleting a memcg?
```

There are two charging functions here:

mem_cgroup_charge_slab() and mem_cgroup_charge_kmem() (the later had its
name changed in my private branch, for the next submission)

The slub allocator will draw large kmalloc allocations directly from the
page allocator, which is the case this function is designed to handle.

Since we have no cache to bill this against, we need to hold the
reference here.

```

>
> We might need to charge memsw here too.
```

hummm, isn't there a more automated way to do that ?

I'll take a look.

> Might need to uncharge memsw.

Here too.

in_interrupt() yes, __GFP_NOFAIL I don't think so.

__GFP_NOFAIL should lead to a res_counter_charge_nofail() in the end.
The name similarity is no coincidence...

 From a code style PoV, it makes sense to bundle an in_interrupt() check
here, but from a performance PoV, putting it in the callers can help us
avoid the price of a function call.

But well, looking at the code, I see it is not there as well... =(

I plan to change memcontrol.h to look like this:

```
static __always_inline struct kmem_cache *
mem_cgroup_get_kmem_cache(struct kmem_cache *cachep, gfp_t gfp)
{
	if (mem_cgroup_kmem_on && current->mm && !in_interrupt())
		return __mem_cgroup_get_kmem_cache(cachep, gfp);
	return cachep;
}
```
