
Subject: vswap question - physpages/oomguarpages

I just noticed a couple of containers on one of our vswap enabled servers have non-zero failcnt's (user_beancounters)

uid	resource	limit	held	maxheld
barrier			failcnt	
1413:				
	physpages		84873	131166
0	131072		61	
	oomguarpages		94628	377952
0	9223372036854775807			4
1409:				
	physpages		52986	262155
0	262144		1378	
	oomguarpages		57155	376725
0	9223372036854775807			18

(I've deleted lines with zero failcnt for clarity)

It was my understanding that if a vswap enabled container try to use more physpages than available it would start "vswapping" - is that what happens here? Otherwise how can physpages fail? Is this normal swapping behavior or a problem?

A second thing is, when I tried to raise the physpages value with vzctl it again wrote the old "block" values into the vz conf files, i.e.

i.e. before running vzctl the values are like this:

```
< PHYSPAGES="0:512M"  
< SWAPPAGES="0:1024M"
```

after running vzctl --set 1413 --save --ram 512M --swap 1G the values are like this:

```
> PHYSPAGES="0:131072"  
> SWAPPAGES="0:262144"
```

I already opened a bug report on this and I thought it had been fixed already. Is there some undocumented flag that needs to be provided to vzctl to get it to write out the values in the easy human readable format?

Regards,
Rene

I guess it means oom, i.e. out of memory killer had to kill someone since vswap+ram was not enough...

A bug report is a bug report. It have status, and whenever something about the bug changes, it is usually reflected in the bug report.

I have replied in that bug report. vzctl was never doing this (ie it was always saving parameters in simple numeric form, without any suffixes). More to day, doing it right requires non-trivial changes, so I set this bug severity to be enhancement.
