Hello,

I am pretty new user of OpenVZ. Therefore, I am having problems setting up my hosting. I went through the forum topics and saw that there is tons of information out there, but I am afraid I will not be able to do without your help.

First of all, I would like to make clear the hardware I am using:

Operating System: CentOS 5 - 32-BIT

RAM/Memory: 1GB DDR2

CPU: Celeron D 347 3.6ghz

I would like to run 1 VPS on the host machine. I would like this VPS to run with 512MB of RAM.

This VPS is intended to host several web sites. All the sites together receive 10k visit per day.

They are photo blogs. I would like to mention that the bandwidth of the sites is pretty high - 2-3TB per month.

The problem is:

Pretty often, when I run a command, I get the followin error:

-bash: fork: Cannot allocate memory

I get this error when I run a simple command, as simple as TOP. Meanwhile, the VPS indicates that it has enough free memory. Accordint to the VPS statistics, it consumes average of 200MB RAM memory. When I created the VPS, I configured it to be with 678MB.

Here is what the cat /proc/user_beancounters command shows:

Version: 2.5

numiptent	20	20	2147483647	2147483647	0

My VPS has na ID of 101.

Please, give me some advice and tell me what settings I should change in order the VPS to be OK.

Thanks in advance!

Is this the only option?
I think the VPS is not configured properly.

Well, with 2.6.32 memory management is easier than is with 2.6.18.
With 2.6.32 you'll need to set every option to unlimited without physpages and swappages.
Then kernel will play automatically with other parameters.

I understand, but I use Kloxo for control panel, which is not supported with centos 6.x
So I think to set manual this options.
