Hey there,

I am completely new to OpenVZ and am running into difficulty when setting up my containers to receive their ip addresses through DHCP rather than having them static.

I'm running CentOS 6.3, kernel Linux 2.6.32-042stab061.2 and the latest openVZ (as far as I'm aware).

I followed the guides:

wiki.openvz.org/Quick_installation

wiki.openvz.org/Basic_operations_in_OpenVZ_environment

wiki.openvz.org/Common_Networking_HOWTOs

to set up OpenVZ and the containers. However, when I'm going through the steps for DHCP supplied addresses in the third link, I come an error when I run the command:

```
[host-node]# ifconfig veth101.0 0
```

when I am met with:

```
SIOCSIFADDR: No such device
```

```
veth101.0: unknown interface: No such device
```

I followed the tutorials to the t, but yet I am stumped by this. I have tried searching any and all resources on the subject I could, but I'm still new to working with both Linux systems and OpenVZ itself.

Any information would be appreciated, or any links to information that I might have missed. (Also, any additional information I might need to give to help)
