+This file contains information about how to use containers. Configfs support  
+is needed in kernel as the container's user interface is through configfs. So  
+first enable CONFIG\_CONFIGFS\_FS and CONFIG\_CONTAINERS and recompile the kernel.

+

+1- Mount a configfs (for example):

+ mount -t configfs none /mnt/configfs

+ This will create a /mnt/configfs mount point.

+

+2- As the support of containers is built into kernel, so the mount point

+ /mnt/configfs will automatically contain a directory "containers"

+

+3- Create a container by name test\_container

+ cd /mnt/configfs/containers

+ mkdir test\_container

+

+All the current implemented attributes in the kernel will show up in the

+directory /configfs/containers/test\_container

+

+4- Add a task to container

+ cd /mnt/configfs/containers/test\_container

+ echo <pid> > addtask

+

+Now the <pid> and its subsequently forked children will belong to container

+test\_container.

+

+5- Remove a task from container

+ echo <pid> rmtask

+

+6- Set a page limit for the container

+ echo some\_number\_of\_pages > page\_limit

+

+7- Read the id for the container

+ cat id

+  
+8- Get the statistics for this container  
+ cat num\* (will print active pages, anon\_pages, file\_pages, num\_files,  
+ and num\_task)  
+ cat \*hits (will print page\_limit\_hits and task\_limit\_hits: the number  
+ of times container has gone over page\_limit and task\_limit)  
+9- Freeing a container  
+ cd /mnt/configs/containers/  
+ rmdir test\_container

echo <pid> > rmtask?

Please also give a short description what containers are for. From what I read here I can only guess it's about getting some statistics about a group of tasks.

Container is like FreeBSD Jail on steroids (and Jail is chroot() on steroids).

As a nice intro, I suggest you to read

[http://en.wikipedia.org/wiki/Operating-system\\_level\\_virtualization](http://en.wikipedia.org/wiki/Operating-system_level_virtualization)

<http://en.wikipedia.org/wiki/OpenVZ>

rmtask is an attribute defined in test\_container directory. So, first you have to cd into container directory (cd /mnt/configs/containers/test\_container and then execute this command)

> Please also give a short description what containers are for. From what I read > here I can only guess it's about getting some statistics about a group of > tasks.

Containers allow different workloads to be run on the same platform with limits defined on per container basis. This basically allows a single platform to be (soft) partitioned among different workloads (each of which could be running many tasks). The limits could be amount of memory, number of tasks among other features. These two features are already implemented in the patch set that I posted. But it is possible to add other controllers like CPU that allows only finite amount of time to the processes belonging to a container.

Currently this patch set is only tracking user memory (both file based and anonymous). The memory handler is currently deactivating pages belonging to a container that has gone over the limit. Even though this allows containers to go over board their limits but 1- once they are over the limit then they run in degraded manner and 2- if there is any memory pressure then the (extra) pages belonging to this container are the prime candidates for swapping (for example). The statistics that are shown in each container directory are the current values of each resource consumption.

Please let me know if you need any more specific information about the patch set.

A general description for the containers needs to go into Documentation/  
along with the usage example, so that potential users know what to do  
with it. The above seems fine, just remove the "this patch" references.

> + cd /mnt/configfs/containers/
> + rmdir test_container
```

What happens if you try to remove a container that still has active tasks? Are you relying on the VFS to catch the 'non-empty directory'? (of course, 'rm -r' has predictable semantics here).

I see support for "add a task" and "remove a task", but none for listing the current tasks in the container?

When a rmdir operation is done on a directory, then all tasks have to  
move out of container (before we the rmdir operation is complete). This  
removal of tasks from a container is done as part of  
container\_remove\_tasks.

This is one of the TODO items that I've listed. Will be there soon.

thanks,
