---

I have little network knowledge, please bare with me.

I want to know if the solution provided on post #14966, titled "**\*SOLVED\*** VEs with different subnets" (can't post links yet) applies to my scenario as well.

That post was supposedly solved with thi article from the wiki:

[Using\\_private\\_IPs\\_for\\_Hardware\\_Nodes](#)

My situation:

The HN has one /29 block working perfectly fine, and it has a second /27 block from a different subnet, statically routed (by the datacenter) to the first IP of the /29 block, which is set for eth0 (first interface/NIC).

The /27 block is to be used for all the containers. I have tried the typical OpenVZ setup and other thing I have found around internet, but when I create a container with an IP of the /27 block, I just can't see the internet from within nor reach it from outside.

Also, I want to be sure that the issue is on my end and not on the datacenter's.

I'm about to hang myself.
