I used a fresh load of CentOS 6.3 (x86\_64) for the host, used the install instructions from the OpenVZ.org site. The versions were the latest stable available today, 20120716. I dropped in a template and loaded 32-bit guest running CentOS 5.9. I fired up scp on another server sn transferred a file to the guest, and the transfer stalled, runnign about 10% of the speed I would have expected after the first few K.

Deciding

I had dome something wrong, I pulled down the latest CentOS 6.4 and installed a new host (also 64-bit) and dropped a guest there using CentOS 5 in 32-bit and tested it. The problem was WORSE! A 2K file transferred in seconds, a larger file stalled and NEVER COMPLETED.

I noted in both cases ssh connections worked fine, and thin odbc packets (small data requests) worked while larger ones broke the connection.

I am dropping back to CentOS 5 in 32-bit for the host, as I have many instances where that is working. I am curious thoug, if I did something wrong by mixing CentOS6 in 64bit as host with CentOS5 32-bit as guests, is this a problem with CentOS6, a problem with something in OpenVZ in the combination, or something I have not even considered?

do I understand you correctly:

you have 2 HN servers with centos6(64bit) and in both of them CT with centos5(32bit) and connection stalls between this CTs?

Traffic stalls between the CT and anything external. the other CT, the remote host, I did not check between the HN and its CT.

Again, if the traffic is 'thin' you will never see the effect. Session over ssh work fine. I suspect telnet would be fine. It is anything where the volume of data is larger that triggers the issue. Since I was able to replicate it so easily (if unhappily) here, I suspect it is repeatable.

UPDATE:: I reloaded one of the boxes with 32-bit CentOS 5.9 and installed OpenVZ, manually migrated the guest over, and there it performed perfectly. The problem seems ONLY to express on CentOS 6.3 and 6.4 64-bit hosts.

I have a 64-bit install of CentOS 5.9 running multiple CentOS 32-bit guests with no problem, so it is not simply a 32 on 64 issue. It seem specific to CentOS 6, though I have not tested enough to prove that it is limited to the 64-bit hosts, or 64-bit host with 32-bit container.

My search for known issues was not exhaustive, but I found nothing that stood out as quite like this. It occurs to me to ask if this problem is limited to MY servers! Were it general, I would think others would have detected it first.

I suggest to file bug report, give instructions how to reproduce and then it will be fixed.

I always hesitate to do that in case it is a known issue, I hate causing development people duplication and distraction (having lived it for many years). I will take your advice and see if we can play.

I understand you, but because I currently don't have time to test and investigate issue I just recommended you best path to solve problem. that's why I suggessted to show how to reproduce bug.
