Is it possible to create a VPS running FC5 on a host with RHEL4 or CentOS4?

I'd think so, but I've yet to be able to get 'vzpkgcache' to build a package cache. Any thoughts?

Can you send us the exact command you are running, the kernel version, and the error message?
Whenever reporting any technical problem, its ideal to include a method for others to duplicate the problem on their end. If this is not possible, such that you have some specific scenario, you will need to provide as much background information as possible.

I'm at home now so I don't have the error messages. I know that the builds of the "default" template were failing because of conflicting packages.

In any case, I forced vzpkgcache to build only fedora-core-5-i386-minimal and that worked just fine. That was all I really wanted anyway.
