Greetings,

I'm running 2.6.16-026test020.1-smp but I've seen it on the 2.6.18 test kernels too... but what does the following mean when logged to /var/log/messages of the physical host?

Dec 3 00:15:05 new kernel: UB: Bad refcount (-2146306411) on put of 0 (c05ff280)

Dec 3 00:15:05 new kernel: UB: Bad refcount (-2146306412) on put of 0 (c05ff280)

I see a zillion of those over and over. I think I'm going to switch back to the 2.6.9 stable to see if that helps.

This is HN beancounter reference leak. Please, file a bug and attach cut of /var/log/messages, where the first of such messages appeared.

Same kernel, same error.

Any solutions except of downgrading?
