Subject: [PATCH 0/7] containers (V7): Generic Process Containers
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:21 GMT
View Forum Message <> Reply to Message

--

This is an update to my multi-hierarchy multi-subsystem generic
process containers patch. Changes since V6 (22nd December) include:

- updated to 2.6.20

- added more details about multiple hierarchy support in the
  documentation

- reduced the per-task memory overhead to one pointer (previously it
  was one pointer for each hierarchy). Now each task has
  a pointer to a container_group, which holds the pointers to the
  containers (one per active hierarchy) that the task is attached to
  and the associated per-subsystem state (one per active subsystem).
  This container group is shared (with reference counts) between all
  tasks that have the same set of container mappings.

- added API support for binding/unbinding subsystems to/from active
  hierarchies, by remounting with -oremount,<new-subsys-list>. Currently
  this fails with EBUSY if the hierarchy has a child containers; full
  implementation support is left to a later patch.

- added a bind() subsystem callback to indicate when a subsystem is
  moved between hierarchies

- added container_clone(subsys, task), which creates a child container
  for the hierarchy that the specified subsystem is bound to, and
  moves the given task into that container. An example use of this
  would be in sys_unshare, which could, if the namespace container
  subsystem is active, create a child container when the new namespace
  is created.

- temporarily removed the "release agent" support. It's only currently
  used by CPUsets, and intrudes somewhat on the per-container
  reference counting. If necessary it can be re-added, either as a
  generic subsystem feature or a CPUset-specific feature, via a kernel
  thread that periodically polls containers that have been designated
  as notify_on_release to see if they are releasable

Generic Process Containers

There have recently been various proposals floating around for

resource management/accounting and other task grouping subsystems in
the kernel, including ResGroups, User BeanCounters, NSProxy
containers, and others. These all need the basic abstraction of being
able to group together multiple processes in an aggregate, in order to
track/limit the resources permitted to those processes, or control
other behaviour of the processes, and all implement this grouping in
different ways.

Already existing in the kernel is the cpuset subsystem; this has a
process grouping mechanism that is mature, tested, and well documented
(particularly with regards to synchronization rules).

This patchset extracts the process grouping code from cpusets into a
generic container system, and makes the cpusets code a client of
the container system.

It also provides several example clients of the container system,
including ResGroups, BeanCounters and namespace proxy.

The change is implemented in three stages, plus four example
subsystems that aren't necessarily intended to be merged as part of
this patch set, but demonstrate the applicability of the framework.

1) extract the process grouping code from cpusets into a standalone system

2) remove the process grouping code from cpusets and hook into the
   container system

3) convert the container system to present a generic multi-hierarchy
   API, and make cpusets a client of that API

4) example of a simple CPU accounting container subsystem

5) example of implementing ResGroups and its numtasks controller over
   generic containers

6) example of implementing BeanCounters and its numfiles counter over
   generic containers

7) example of integrating the namespace isolation code (sys_unshare()
   or various clone flags) with generic containers, allowing virtual
   servers to take advantage of other resource control efforts.

The intention is that the various resource management and
virtualization efforts can also become container clients, with the
result that:

- the userspace APIs are (somewhat) normalised

- it's easier to test out e.g. the ResGroups CPU controller in
 conjunction with the BeanCounters memory controller, or use either of
them as the resource-control portion of a virtual server system.

- the additional kernel footprint of any of the competing resource
 management systems is substantially reduced, since it doesn't need
 to provide process grouping/containment, hence improving their
 chances of getting into the kernel

Subject: [PATCH 1/7] containers (V7): Generic container system abstracted from cpusets code
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:22 GMT

View Forum Message <> Reply to Message

This patch creates a generic process container system based on (and
parallel top) the cpusets code. At a coarse level it was created by
copying kernel/cpuset.c, doing s/cpuset/container/g, and stripping out any
code that was cpuset-specific rather than applicable to any process
container subsystem.

+
+/*
+ * We have two global container mutexes below.  They can nest.
+ * It is ok to first take manage_mutex, then nest callback_mutex.  We also
+ * require taking task_lock() when dereferencing a tasks container pointer.
+ * See "The task_lock() exception", at the end of this comment.
+ *
+ * A task must hold both mutexes to modify containers.  If a task
+ * holds manage_mutex, then it blocks others wanting that mutex,
+ * ensuring that it is the only task able to also acquire callback_mutex
+ * and be able to modify containers.  It can perform various checks on
+ * the container structure first, knowing nothing will change.  It can
+ * also allocate memory while just holding manage_mutex.  While it is
+ * performing these checks, various callback routines can briefly
+ * acquire callback_mutex to query containers.  Once it is ready to make
+ * the changes, it takes callback_mutex, blocking everyone else.
+ *
+ * Calls to the kernel memory allocator can not be made while holding
+ * callback_mutex, as that would risk double tripping on callback_mutex
+ * from one of the callbacks into the container code from within
+ * __alloc_pages().
+ *
+ * If a task is only holding callback_mutex, then it has read-only
+ * access to containers.
+ *
+ * The task_struct fields mems_allowed and mems_generation may only
+ * be accessed in the context of that task, so require no locks.
+ *
+ * Any task can increment and decrement the count field without lock.
+ * So in general, code holding manage_mutex or callback_mutex can't rely
+ * on the count field not changing.  However, if the count goes to
+ * zero, then only attach_task(), which holds both mutexes, can
+ * increment it again.  Because a count of zero means that no tasks
+ * are currently attached, therefore there is no way a task attached
+ * to that container can fork (the other way to increment the count).
+ * So code holding manage_mutex or callback_mutex can safely assume that
+ * if the count is zero, it will stay zero.  Similarly, if a task
+ * holds manage_mutex or callback_mutex on a container with zero count, it
+ * knows that the container won't be removed, as container_rmdir() needs
```

```
+ * both of those mutexes.
+ *
+ * The container_common_file_write handler for operations that modify
+ * the container hierarchy holds manage_mutex across the entire operation,
+ * single threading all such container modifications across the system.
+ *
+ * The container_common_file_read() handlers only hold callback_mutex across
+ * small pieces of code, such as when reading out possibly multi-word
+ * cpumasks and nodemasks.
+ *
+ * The fork and exit callbacks container_fork() and container_exit(), don't
+ * (usually) take either mutex.  These are the two most performance
+ * critical pieces of code here.  The exception occurs on container_exit(),
+ * when a task in a notify_on_release container exits.  Then manage_mutex
+ * is taken, and if the container count is zero, a usermode call made
+ * to /sbin/container_release_agent with the name of the container (path
+ * relative to the root of container file system) as the argument.
+ *
+ * A container can only be deleted if both its 'count' of using tasks
+ * is zero, and its list of 'children' containers is empty.  Since all
+ * tasks in the system use _some_ container, and since there is always at
+ * least one task in the system (init, pid == 1), therefore, top_container
+ * always has either children containers and/or using tasks.  So we don't
+ * need a special hack to ensure that top_container cannot be deleted.
+ *
+ * The above "Tale of Two Semaphores" would be complete, but for:
+ *
+ * The task_lock() exception
+ *
+ * The need for this exception arises from the action of attach_task(),
+ * which overwrites one tasks container pointer with another.  It does
+ * so using both mutexes, however there are several performance
+ * critical places that need to reference task->container without the
+ * expense of grabbing a system global mutex.  Therefore except as
+ * noted below, when dereferencing or, as in attach_task(), modifying
+ * a tasks container pointer we use task_lock(), which acts on a spinlock
+ * (task->alloc_lock) already in the task_struct routinely used for
+ * such matters.
+ *
+ * P.S.  One more locking exception.  RCU is used to guard the
+ * update of a tasks container pointer by attach_task() and the
+ * access of task->container->mems_generation via that pointer in
+ * the routine container_update_task_memory_state().

+ * Notify userspace when a container is released, by running
+ * /sbin/container_release_agent with the name of the container (path
+ * relative to the root of container file system) as the argument.
+ *
+ * Most likely, this user command will try to rmdir this container.
+ *
+ * This races with the possibility that some other task will be
+ * attached to this container before it is removed, or that some other
+ * user task will 'mkdir' a child container of this container.  That's ok.
+ * The presumed 'rmdir' will fail quietly if this container is no longer
+ * unused, and this container will be reprieved from its death sentence,
+ * to continue to serve a useful existence.  Next time it's released,
+ * we will get notified again, if it still has 'notify_on_release' set.
+ *
```

```
+ * The final arg to call_usermodehelper() is 0, which means don't
+ * wait.  The separate /sbin/container_release_agent task is forked by
+ * call_usermodehelper(), then control in this thread returns here,
+ * without waiting for the release agent task.  We don't bother to
+ * wait because the caller of this routine has no use for the exit
+ * status of the /sbin/container_release_agent task, so no sense holding
+ * our caller up for that.
+ *
+ * When we had only one container mutex, we had to call this
+ * without holding it, to avoid deadlock when call_usermodehelper()
+ * allocated memory.  With two locks, we could now call this while
+ * holding manage_mutex, but we still don't, so as to minimize
+ * the time manage_mutex is held.

+/**
+ * container_exit - detach container from exiting task
+ * @tsk: pointer to task_struct of exiting process
+ *
+ * Description: Detach container from @tsk and release it.
+ *
+ * Note that containers marked notify_on_release force every task in
+ * them to take the global manage_mutex mutex when exiting.
+ * This could impact scaling on very large systems.  Be reluctant to
+ * use notify_on_release containers where very high task exit scaling
+ * is required on large systems.
+ *
```

```
+ * Don't even think about derefencing 'cont' after the container use count
+ * goes to zero, except inside a critical section guarded by manage_mutex
+ * or callback_mutex.   Otherwise a zero container use count is a license to
+ * any other task to nuke the container immediately, via container_rmdir().
+ *
+ * This routine has to take manage_mutex, not callback_mutex, because
+ * it is holding that mutex while calling check_for_release(),
+ * which calls kmalloc(), so can't be called holding callback_mutex().
+ *
+ * We don't need to task_lock() this reference to tsk->container,
+ * because tsk is already marked PF_EXITING, so attach_task() won't
+ * mess with it, or task is a failed fork, never visible to attach_task.
+ *
+ * the_top_container_hack:
+ *
+ *    Set the exiting tasks container to the root container (top_container).
+ *
+ *    Don't leave a task unable to allocate memory, as that is an
+ *    accident waiting to happen should someone add a callout in
+ *    do_exit() after the container_exit() call that might allocate.
+ *    If a task tries to allocate memory with an invalid container,
+ *    it will oops in container_update_task_memory_state().
+ *
+ *    We call container_exit() while the task is still competent to
+ *    handle notify_on_release(), then leave the task attached to
+ *    the root container (top_container) for the remainder of its exit.
+ *
+ *    To do this properly, we would increment the reference count on
+ *    top_container, and near the very end of the kernel/exit.c do_exit()
+ *    code we would add a second container function call, to drop that
+ *    reference.  This would just create an unnecessary hot spot on
+ *    the top_container reference count, to no avail.
+ *
+ *    Normally, holding a reference to a container without bumping its
+ *    count is unsafe.   The container could go away, or someone could
+ *    attach us to a different container, decrementing the count on
+ *    the first container that we never incremented.  But in this case,
+ *    top_container isn't going away, and either task has PF_EXITING set,
+ *    which wards off any attach_task() attempts, or task is a failed
+ *    fork, never visible to attach_task.
+ *
+ *    Another way to do this would be to set the container pointer
+ *    to NULL here, and check in container_update_task_memory_state()
+ *    for a NULL pointer.  This hack avoids that NULL check, for no
+ *    cost (other than this way too long comment ;).
+ **/

+1. Containers
+==========
+
+1.1 What are containers ?
+----------------------
+
+Containers provide a mechanism for aggregating sets of tasks, and all
+their children, into hierarchical groups.
+
+Each task has a pointer to a container. Multiple tasks may reference
+the same container. User level code may create and destroy containers
+by name in the container virtual file system, specify and query to
+which container a task is assigned, and list the task pids assigned to
+a container.
+
+On their own, the only use for containers is for simple job
+tracking. The intention is that other subsystems, such as cpusets (see
+Documentation/cpusets.txt) hook into the generic container support to
+provide new attributes for containers, such as accounting/limiting the
+resources which processes in a container can access.
+
+1.2 Why are containers needed ?
+----------------------------
+
+There are multiple efforts to provide process aggregations in the
+Linux kernel, mainly for resource tracking purposes. Such efforts
+include cpusets, CKRM/ResGroups, and UserBeanCounters. These all
+require the basic notion of a grouping of processes, with newly forked
+processes ending in the same group (container) as their parent
+process.
+
+The kernel container patch provides the minimum essential kernel
+mechanisms required to efficiently implement such groups. It has
+minimal impact on the system fast paths, and provides hooks for
+specific subsystems such as cpusets to provide additional behaviour as
+desired.
+
+
+1.3 How are containers implemented ?
+---------------------------------
+
+Containers extends the kernel as follows:
+
+ - Each task in the system is attached to a container, via a pointer
+   in the task structure to a reference counted container structure.

+ - The hierarchy of containers can be mounted at /dev/container (or
+   elsewhere), for browsing and manipulation from user space.
+ - You can list all the tasks (by pid) attached to any container.
+
+The implementation of containers requires a few, simple hooks
+into the rest of the kernel, none in performance critical paths:
+
+ - in init/main.c, to initialize the root container at system boot.
+ - in fork and exit, to attach and detach a task from its container.
+
+In addition a new file system, of type "container" may be mounted,
+typically at /dev/container, to enable browsing and modifying the containers
+presently known to the kernel. No new system calls are added for
+containers - all support for querying and modifying containers is via
+this container file system.
+
+Each task under /proc has an added file named 'container', displaying
+the container name, as the path relative to the root of the container file
+system.
+
+Each container is represented by a directory in the container file system
+containing the following files describing that container:
+
+ - tasks: list of tasks (by pid) attached to that container
+ - notify_on_release flag: run /sbin/container_release_agent on exit?
+
+Other subsystems such as cpusets may add additional files in each
+container dir
+
+New containers are created using the mkdir system call or shell
+command. The properties of a container, such as its flags, are
+modified by writing to the appropriate file in that containers
+directory, as listed above.
+
+The named hierarchical structure of nested containers allows partitioning
+a large system into nested, dynamically changeable, "soft-partitions".
+
+The attachment of each task, automatically inherited at fork by any
+children of that task, to a container allows organizing the work load
+on a system into related sets of tasks. A task may be re-attached to
+any other container, if allowed by the permissions on the necessary
+container file system directories.
+
+The use of a Linux virtual file system (vfs) to represent the
+container hierarchy provides for a familiar permission and name space
+for containers, with a minimum of additional kernel code.
+
+1.4 What does notify_on_release do ?

+----------------------------------
+
+If the notify_on_release flag is enabled (1) in a container, then whenever
+the last task in the container leaves (exits or attaches to some other
+container) and the last child container of that container is removed, then
+the kernel runs the command /sbin/container_release_agent, supplying the
+pathname (relative to the mount point of the container file system) of the
+abandoned container. This enables automatic removal of abandoned containers.
+The default value of notify_on_release in the root container at system
+boot is disabled (0). The default value of other containers at creation
+is the current value of their parents notify_on_release setting.
+
+1.5 How do I use containers ?
+-------------------------
+
+To start a new job that is to be contained within a container, the steps are:
+
+ 1) mkdir /dev/container
+ 2) mount -t container container /dev/container
+ 3) Create the new container by doing mkdir's and write's (or echo's) in
+   the /dev/container virtual file system.
+ 4) Start a task that will be the "founding father" of the new job.
+ 5) Attach that task to the new container by writing its pid to the
+   /dev/container tasks file for that container.
+ 6) fork, exec or clone the job tasks from this founding father task.
+
+For example, the following sequence of commands will setup a container
+named "Charlie", containing just CPUs 2 and 3, and Memory Node 1,
+and then start a subshell 'sh' in that container:
+
+ mount -t container none /dev/container
+ cd /dev/container
+ mkdir Charlie
+ cd Charlie
+ /bin/echo $$ > tasks
+ sh
+ # The subshell 'sh' is now running in container Charlie
+ # The next line should display '/Charlie'
+ cat /proc/self/container
+
+In the future, a C library interface to containers will likely be
+available. For now, the only way to query or modify containers is
+via the container file system, using the various cd, mkdir, echo, cat,
+rmdir commands from the shell, or their equivalent from C.
+
+2. Usage Examples and Syntax
+============================
+

+2.1 Basic Usage
+---------------
+
+Creating, modifying, using the containers can be done through the container
+virtual filesystem.
+
+To mount it, type:
+# mount -t container none /dev/container
+
+Then under /dev/container you can find a tree that corresponds to the
+tree of the containers in the system. For instance, /dev/container
+is the container that holds the whole system.
+
+If you want to create a new container under /dev/container:
+# cd /dev/container
+# mkdir my_container
+
+Now you want to do something with this container.
+# cd my_container
+
+In this directory you can find several files:
+# ls
+notify_on_release tasks
+
+Now attach your shell to this container:
+# /bin/echo $$ > tasks
+
+You can also create containers inside your container by using mkdir in this
+directory.
+# mkdir my_sub_cs
+
+To remove a container, just use rmdir:
+# rmdir my_sub_cs
+This will fail if the container is in use (has containers inside, or has
+processes attached).
+
+2.2 Attaching processes
+-----------------------
+
+# /bin/echo PID > tasks
+
+Note that it is PID, not PIDs. You can only attach ONE task at a time.
+If you have several tasks to attach, you have to do it one after another:
+
+# /bin/echo PID1 > tasks
+# /bin/echo PID2 > tasks
+ ...
+# /bin/echo PIDn > tasks

+
+
+3. Questions
+============
+
+Q: what's up with this '/bin/echo' ?
+A: bash's builtin 'echo' command does not check calls to write() against
+   errors. If you use it in the container file system, you won't be
+   able to tell whether a command succeeded or failed.
+
+Q: When I attach processes, only the first of the line gets really attached !
+A: We can only return one error code per call to write(). So you should also
+   put only ONE pid.
+

Subject: [PATCH 2/7] containers (V7): Cpusets hooked into containers
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:23 GMT
View Forum Message <> Reply to Message

This patch removes the process grouping code from the cpusets code,
instead hooking it into the generic container system. This temporarily
adds cpuset-specific code in kernel/container.c, which is removed by
the next patch in the series.

- * We have two global cpuset mutexes below.  They can nest.
- * It is ok to first take manage_mutex, then nest callback_mutex.  We also
- * require taking task_lock() when dereferencing a tasks cpuset pointer.
- * See "The task_lock() exception", at the end of this comment.
- *
- * A task must hold both mutexes to modify cpusets.  If a task
- * holds manage_mutex, then it blocks others wanting that mutex,
- * ensuring that it is the only task able to also acquire callback_mutex
- * and be able to modify cpusets.  It can perform various checks on
- * the cpuset structure first, knowing nothing will change.  It can
- * also allocate memory while just holding manage_mutex.  While it is
- * performing these checks, various callback routines can briefly
- * acquire callback_mutex to query cpusets.  Once it is ready to make
```

- * the changes, it takes callback_mutex, blocking everyone else.
- *
- * Calls to the kernel memory allocator can not be made while holding
- * callback_mutex, as that would risk double tripping on callback_mutex
- * from one of the callbacks into the cpuset code from within
- * __alloc_pages().
- *
- * If a task is only holding callback_mutex, then it has read-only
- * access to cpusets.
- *
- * The task_struct fields mems_allowed and mems_generation may only
- * be accessed in the context of that task, so require no locks.
- *
- * Any task can increment and decrement the count field without lock.
- * So in general, code holding manage_mutex or callback_mutex can't rely
- * on the count field not changing. However, if the count goes to
- * zero, then only attach_task(), which holds both mutexes, can
- * increment it again. Because a count of zero means that no tasks
- * are currently attached, therefore there is no way a task attached
- * to that cpuset can fork (the other way to increment the count).
- * So code holding manage_mutex or callback_mutex can safely assume that
- * if the count is zero, it will stay zero. Similarly, if a task
- * holds manage_mutex or callback_mutex on a cpuset with zero count, it
- * knows that the cpuset won't be removed, as cpuset_rmdir() needs
- * both of those mutexes.
- *
- * The cpuset_common_file_write handler for operations that modify
- * the cpuset hierarchy holds manage_mutex across the entire operation,
- * single threading all such cpuset modifications across the system.
- *
- * The cpuset_common_file_read() handlers only hold callback_mutex across
- * small pieces of code, such as when reading out possibly multi-word
- * cpumasks and nodemasks.
- *
- * The fork and exit callbacks cpuset_fork() and cpuset_exit(), don't
- * (usually) take either mutex. These are the two most performance
- * critical pieces of code here. The exception occurs on cpuset_exit(),
- * when a task in a notify_on_release cpuset exits. Then manage_mutex
- * is taken, and if the cpuset count is zero, a usermode call made
- * to /sbin/cpuset_release_agent with the name of the cpuset (path
- * relative to the root of cpuset file system) as the argument.
- *
- * A cpuset can only be deleted if both its 'count' of using tasks
- * is zero, and its list of 'children' cpusets is empty. Since all
- * tasks in the system use _some_ cpuset, and since there is always at
- * least one task in the system (init), therefore, top_cpuset
- * always has either children cpusets and/or using tasks. So we don't
- * need a special hack to ensure that top_cpuset cannot be deleted.

```
- *
- * The above "Tale of Two Semaphores" would be complete, but for:
- *
- * The task_lock() exception
- *
- * The need for this exception arises from the action of attach_task(),
- * which overwrites one tasks cpuset pointer with another.  It does
- * so using both mutexes, however there are several performance
- * critical places that need to reference task->cpuset without the
- * expense of grabbing a system global mutex.  Therefore except as
- * noted below, when dereferencing or, as in attach_task(), modifying
- * a tasks cpuset pointer we use task_lock(), which acts on a spinlock
- * (task->alloc_lock) already in the task_struct routinely used for
- * such matters.
- *
- * P.S.  One more locking exception.  RCU is used to guard the
- * update of a tasks cpuset pointer by attach_task() and the
- * access of task->cpuset->mems_generation via that pointer in
- * the routine cpuset_update_task_memory_state().

 /**
- * cpuset_fork - attach newly forked task to its parents cpuset.
- * @tsk: pointer to task_struct of forking parent process.
- *
- * Description: A task inherits its parent's cpuset at fork().
- *
- * A pointer to the shared cpuset was automatically copied in fork.c
- * by dup_task_struct().  However, we ignore that copy, since it was
- * not made under the protection of task_lock(), so might no longer be
- * a valid cpuset pointer.  attach_task() might have already changed
- * current->cpuset, allowing the previously referenced cpuset to
- * be removed and freed.  Instead, we task_lock(current) and copy
- * its present value of current->cpuset for our freshly forked child.
- *
- * At the point that cpuset_fork() is called, 'current' is the parent
- * task, and the passed argument 'child' points to the child task.
- **/

-
-/**
- * cpuset_exit - detach cpuset from exiting task
- * @tsk: pointer to task_struct of exiting process
- *
- * Description: Detach cpuset from @tsk and release it.
- *
- * Note that cpusets marked notify_on_release force every task in
- * them to take the global manage_mutex mutex when exiting.
- * This could impact scaling on very large systems.  Be reluctant to
- * use notify_on_release cpusets where very high task exit scaling
- * is required on large systems.
- *
- * Don't even think about derefencing 'cs' after the cpuset use count
- * goes to zero, except inside a critical section guarded by manage_mutex
- * or callback_mutex.   Otherwise a zero cpuset use count is a license to
- * any other task to nuke the cpuset immediately, via cpuset_rmdir().
- *
- * This routine has to take manage_mutex, not callback_mutex, because
- * it is holding that mutex while calling check_for_release(),
- * which calls kmalloc(), so can't be called holding callback_mutex().
- *
- * We don't need to task_lock() this reference to tsk->cpuset,
- * because tsk is already marked PF_EXITING, so attach_task() won't
- * mess with it, or task is a failed fork, never visible to attach_task.
- *
- * the_top_cpuset_hack:
- *
- *    Set the exiting tasks cpuset to the root cpuset (top_cpuset).
- *
- *    Don't leave a task unable to allocate memory, as that is an
- *    accident waiting to happen should someone add a callout in
- *    do_exit() after the cpuset_exit() call that might allocate.
- *    If a task tries to allocate memory with an invalid cpuset,
- *    it will oops in cpuset_update_task_memory_state().
- *
- *    We call cpuset_exit() while the task is still competent to
- *    handle notify_on_release(), then leave the task attached to
- *    the root cpuset (top_cpuset) for the remainder of its exit.
- *
- *    To do this properly, we would increment the reference count on
- *    top_cpuset, and near the very end of the kernel/exit.c do_exit()
- *    code we would add a second cpuset function call, to drop that
```

```
- *    reference.  This would just create an unnecessary hot spot on
- *    the top_cpuset reference count, to no avail.
- *
- *    Normally, holding a reference to a cpuset without bumping its
- *    count is unsafe.   The cpuset could go away, or someone could
- *    attach us to a different cpuset, decrementing the count on
- *    the first cpuset that we never incremented.  But in this case,
- *    top_cpuset isn't going away, and either task has PF_EXITING set,
- *    which wards off any attach_task() attempts, or task is a failed
- *    fork, never visible to attach_task.
- *
- *    Another way to do this would be to set the cpuset pointer
- *    to NULL here, and check in cpuset_update_task_memory_state()
- *    for a NULL pointer.  This hack avoids that NULL check, for no
- *    cost (other than this way too long comment ;).

Subject: [PATCH 3/7] containers (V7): Add generic multi-subsystem API to containers
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:24 GMT
View Forum Message <> Reply to Message

This patch removes all cpuset-specific knowlege from the container
system, replacing it with a generic API that can be used by multiple
subsystems. Cpusets is adapted to be a container subsystem.

Signed-off-by: Paul Menage <menage@google.com>

  * We have two global container mutexes below.  They can nest.
@@ -156,44 +307,109 @@ static struct super_block *container_sb;
  * small pieces of code, such as when reading out possibly multi-word
  * cpumasks and nodemasks.
  *
- * The fork and exit callbacks container_fork() and container_exit(), don't
- * (usually) take either mutex.  These are the two most performance
- * critical pieces of code here.  The exception occurs on container_exit(),
- * when a task in a notify_on_release container exits.  Then manage_mutex
- * is taken, and if the container count is zero, a usermode call made
- * to /sbin/container_release_agent with the name of the container (path
- * relative to the root of container file system) as the argument.
- *
- * A container can only be deleted if both its 'count' of using tasks
- * is zero, and its list of 'children' containers is empty.  Since all
- * tasks in the system use _some_ container, and since there is always at
- * least one task in the system (init, pid == 1), therefore, top_container
- * always has either children containers and/or using tasks.  So we don't
+ * The fork and exit callbacks container_fork() and container_exit(),
+ * don't take either mutex, unless some subsystem has registered a
+ * fork/exit callback.
+ *
+ * A container can only be deleted if all three conditions below hold:
+ *
+ * - its 'count' of using container groups is zero
+ * - its list of 'children' containers is empty.
+ * - all of its subsystems' state records have a zero 'refcnt'
+ *
+ * Since all tasks in the system use _some_ container group, and since
+ * there is always at least one task in the system (init, pid == 1),
+ * therefore, the top_container in each hierarchy always has either
+ * children containers and/or using container groups.  So we don't
  * need a special hack to ensure that top_container cannot be deleted.
  *
  * The above "Tale of Two Semaphores" would be complete, but for:
  *
  * The task_lock() exception
  *
- * The need for this exception arises from the action of attach_task(),
- * which overwrites one tasks container pointer with another.  It does
- * so using both mutexes, however there are several performance
- * critical places that need to reference task->container without the
- * expense of grabbing a system global mutex.  Therefore except as
- * noted below, when dereferencing or, as in attach_task(), modifying
- * a tasks container pointer we use task_lock(), which acts on a spinlock
+ * The need for this exception arises from the action of
+ * attach_task(), which overwrites a task's container group pointer
+ * with a pointer to a different group.  It does so using both
```

```
+ * mutexes, however there are several performance critical places that
+ * need to reference task->containers without the expense of grabbing
+ * a system global mutex.  Therefore except as noted below, when
+ * dereferencing or, as in attach_task(), modifying a task's
+ * containers pointer we use task_lock(), which acts on a spinlock
  * (task->alloc_lock) already in the task_struct routinely used for
  * such matters.
  *
  * P.S.  One more locking exception.  RCU is used to guard the
- * update of a tasks container pointer by attach_task() and the
+ * update of a task's containers pointer by attach_task() and the
  * access of task->container->mems_generation via that pointer in
  * the routine container_update_task_memory_state().
+ *
+ * Some container subsystems and other external code also use these
+ * mutexes, exposed through the container_lock()/container_unlock()
+ * and container_manage_lock()/container_manage_unlock() functions.
+ *
+ * E.g. the out of memory (OOM) code needs to prevent containers from
+ * being changed while it scans the tasklist looking for a task in an
+ * overlapping container. The tasklist_lock is a spinlock, so must be
+ * taken inside callback_mutex.
+ *
+ * Some container subsystems (including cpusets) also use
+ * callback_mutex as a primary lock for synchronizing access to
+ * subsystem state. Deciding on best practices of when to use
+ * fine-grained locks vs container_lock()/container_unlock() is still
+ * a TODO.
+ *
+ * Note that manage_mutex and callback_mutex should both nest inside
+ * any inode->i_mutex, unless the inode isn't accessible to any code
+ * outside the current thread.

 /*
- * Notify userspace when a container is released, by running
- * /sbin/container_release_agent with the name of the container (path
- * relative to the root of container file system) as the argument.
- *
- * Most likely, this user command will try to rmdir this container.
```

```
- *
- * This races with the possibility that some other task will be
- * attached to this container before it is removed, or that some other
- * user task will 'mkdir' a child container of this container.  That's ok.
- * The presumed 'rmdir' will fail quietly if this container is no longer
- * unused, and this container will be reprieved from its death sentence,
- * to continue to serve a useful existence.  Next time it's released,
- * we will get notified again, if it still has 'notify_on_release' set.
- *
- * The final arg to call_usermodehelper() is 0, which means don't
- * wait.  The separate /sbin/container_release_agent task is forked by
- * call_usermodehelper(), then control in this thread returns here,
- * without waiting for the release agent task.  We don't bother to
- * wait because the caller of this routine has no use for the exit
- * status of the /sbin/container_release_agent task, so no sense holding
- * our caller up for that.
- *
- * When we had only one container mutex, we had to call this
- * without holding it, to avoid deadlock when call_usermodehelper()
- * allocated memory.  With two locks, we could now call this while
- * holding manage_mutex, but we still don't, so as to minimize
- * the time manage_mutex is held.
+ * Attach task 'tsk' to container 'cont'
+ *
+ * Call holding manage_mutex.  May take callback_mutex and task_lock of
+ * the task 'pid' during call.

 1.1 What are containers ?

-Containers provide a mechanism for aggregating sets of tasks, and all
-their children, into hierarchical groups.
+Containers provide a mechanism for aggregating/partitioning sets of
+tasks, and all their future children, into hierarchical groups with
+specialized behaviour.
+
+Definitions:
+
+A *container* associates a set of tasks with a set of parameters for one
+or more subsystems.
+
+A *subsystem* is a module that makes use of the task grouping
+facilities provided by containers to treat groups of tasks in
+particular ways. A subsystem is typically a "resource controller" that
+schedules a resource or applies per-container limits, but it may be
+anything that wants to act on a group of processes, e.g. a
+virtualization subsystem.
+
+A *hierarchy* is a set of containers arranged in a tree, such that
+every task in the system is in exactly one of the containers in the
+hierarchy, and a set of subsystems; each subsystem has system-specific
+state attached to each container in the hierarchy. Each hierarchy has
+an instance of the container virtual filesystem associated with it.
+
+At any one time there may be up to CONFIG_MAX_CONTAINER_HIERARCHIES
+active hierachies of task containers. Each hierarchy is a partition of
+all tasks in the system.

-Each task has a pointer to a container. Multiple tasks may reference
-the same container. User level code may create and destroy containers
-by name in the container virtual file system, specify and query to
+User level code may create and destroy containers by name in an
+instance of the container virtual file system, specify and query to
 which container a task is assigned, and list the task pids assigned to
-a container.
+a container. Those creations and assignments only affect the hierarchy
+associated with that instance of the container file system.

 On their own, the only use for containers is for simple job
-tracking. The intention is that other subsystems, such as cpusets (see
-Documentation/cpusets.txt) hook into the generic container support to
-provide new attributes for containers, such as accounting/limiting the
-resources which processes in a container can access.
+tracking. The intention is that other subsystems hook into the generic

+container support to provide new attributes for containers, such as
+accounting/limiting the resources which processes in a container can
+access. For example, cpusets (see Documentation/cpusets.txt) allows
+you to associate a set of CPUs and a set of memory nodes with the
+tasks in each container.

 1.2 Why are containers needed ?

 There are multiple efforts to provide process aggregations in the
 Linux kernel, mainly for resource tracking purposes. Such efforts
-include cpusets, CKRM/ResGroups, and UserBeanCounters. These all
-require the basic notion of a grouping of processes, with newly forked
-processes ending in the same group (container) as their parent
-process.
+include cpusets, CKRM/ResGroups, UserBeanCounters, and virtual server
+namespaces. These all require the basic notion of a
+grouping/partitioning of processes, with newly forked processes ending
+in the same group (container) as their parent process.

 The kernel container patch provides the minimum essential kernel
 mechanisms required to efficiently implement such groups. It has
@@ -61,33 +89,130 @@ minimal impact on the system fast paths,
 specific subsystems such as cpusets to provide additional behaviour as
 desired.

+Multiple hierarchy support is provided to allow for situations where
+the division of tasks into containers is distinctly different for
+different subsystems - having parallel hierarchies allows each
+hierarchy to be a natural division of tasks, without having to handle
+complex combinations of tasks that would be present if several
+unrelated subsystems needed to be forced into the same tree of
+containers.
+
+At one extreme, each resource controller or subsystem could be in a
+separate hierarchy; at the other extreme, all subsystems
+would be attached to the same hierarchy.
+
+As an example of a scenario (originally proposed by vatsa@in.ibm.com)
+that can benefit from multiple hierarchies, consider a large
+university server with various users - students, professors, system
+tasks etc. The resource planning for this server could be along the
+following lines:
+
+   CPU :   Top cpuset
+   /   \
+   CPUSet1   CPUSet2
+ | |

+ (Profs) (Students)
+
+ In addition (system tasks) are attached to topcpuset (so
+ that they can run anywhere) with a limit of 20%
+
+ Memory : Professors (50%), students (30%), system (20%)
+
+ Disk : Prof (50%), students (30%), system (20%)
+
+ Network : WWW browsing (20%), Network File System (60%), others (20%)
+ / \
+ Prof (15%) students (5%)
+
+Browsers like firefox/lynx go into the WWW network class, while (k)nfsd go
+into NFS network class.
+
+At the same time firefox/lynx will share an appropriate CPU/Memory class
+depending on who launched it (prof/student).
+
+With the ability to classify tasks differently for different resources
+(by putting those resource subsystems in different hierarchies) then
+the admin can easily set up a script which receives exec notifications
+and depending on who is launching the browser he can
+
+ # echo browser_pid > /mnt/<restype>/<userclass>/tasks
+
+With only a single hierarchy, he now would potentially have to create
+a separate container for every browser launched and associate it with
+approp network and other resource class. This may lead to
+proliferation of such containers.
+
+Also lets say that the administrator would like to give enhanced network
+access temporarily to a student's browser (since it is night and the user
+wants to do online gaming :) OR give one of the students simulation
+apps enhanced CPU power,
+
+With ability to write pids directly to resource classes, its just a
+matter of :
+
+ # echo pid > /mnt/network/<new_class>/tasks
+ (after some time)
+ # echo pid > /mnt/network/<orig_class>/tasks
+
+Without this ability, he would have to split the container into
+multiple separate ones and then associate the new containers with the
+new resource classes.
+
+

1.3 How are containers implemented ?

Containers extends the kernel as follows:

- - Each task in the system is attached to a container, via a pointer
-   in the task structure to a reference counted container structure.
- - The hierarchy of containers can be mounted at /dev/container (or
-   elsewhere), for browsing and manipulation from user space.
+ - Each task in the system has a reference-counted pointer to a
+   container_group.
+
+ - A container_group contains a set of reference-counted pointers to
+   containers, one in each hierarchy in the system.
+
+ - A container hierarchy filesystem can be mounted for browsing and
+   manipulation from user space.
+
  - You can list all the tasks (by pid) attached to any container.

The implementation of containers requires a few, simple hooks
into the rest of the kernel, none in performance critical paths:

- - in init/main.c, to initialize the root container at system boot.
- - in fork and exit, to attach and detach a task from its container.
+ - in init/main.c, to initialize the root containers and initial
+   container_group at system boot.

-In addition a new file system, of type "container" may be mounted,
-typically at /dev/container, to enable browsing and modifying the containers
-presently known to the kernel. No new system calls are added for
-containers - all support for querying and modifying containers is via
-this container file system.
+ - in fork and exit, to attach and detach a task from its container_group.

-Each task under /proc has an added file named 'container', displaying
-the container name, as the path relative to the root of the container file
-system.
+In addition a new file system, of type "container" may be mounted, to
+enable browsing and modifying the containers presently known to the
+kernel. When mounting a container hierarchy, you may specify a
+comma-separated list of subsystems to mount as the filesystem mount
+options. By default, mounting the container filesystem attempts to
+mount a hierarchy containing all registered subsystems.
+
+If an active hierarchy with exactly the same set of subsystems already
+exists, it will be reused for the new mount. If no existing hierarchy

```
+matches, and any of the requested subsystems are in use in an existing
+hierarchy, the mount will fail with -EBUSY. Otherwise, a new hierarchy
+is activated, associated with the requested subsystems.
+
+It's not currently possible to bind a new subsystem to an active
+container hierarchy, or to unbind a subsystem from an active container
+hierarchy. This may be possible in future, but is fraught with nasty
+error-recovery issues.
+
+When a container filesystem is unmounted, if there are any
+subcontainers created below the top-level container, that hierarchy
+will remain active even though unmounted; if there are no
+subcontainers then the hierarchy will be deactivated.
+
+No new system calls are added for containers - all support for
+querying and modifying containers is via this container file system.
+
+Each task under /proc has an added file named 'container' displaying,
+for each active hierarchy, the subsystem names and the container name
+as the path relative to the root of the container file system.

 Each container is represented by a directory in the container file system
 containing the following files describing that container:
@@ -112,6 +237,14 @@ on a system into related sets of tasks.
 any other container, if allowed by the permissions on the necessary
 container file system directories.

+When a task is moved from one container to another, it gets a new
+container_group pointer - if there's an already existing
+container_group with the desired collection of containers then that
+group is reused, else a new container_group is allocated. Note that
+the current implementation uses a linear search to locate an
+appropriate existing container_group, so isn't very efficient. A
+future version will use a hash table for better performance.
+
 The use of a Linux virtual file system (vfs) to represent the
 container hierarchy provides for a familiar permission and name space
 for containers, with a minimum of additional kernel code.

+3. Kernel API
+=============
+
+3.1 Overview
+------------
+
+Each kernel subsystem that wants to hook into the generic container
+system needs to create a container_subsys object. This contains
+various methods, which are callbacks from the container system, along
+with a subsystem id which will be assigned by the container system.
+
+Other fields in the container_subsys object include:
+
+- subsys_id: a unique array index for the subsystem, indicating which
+ entry in container->subsys[] this subsystem should be
+ managing. Initialized by container_register_subsys(); prior to this
+ it should be initialized to -1
+
+- hierarchy: an index indicating which hierarchy, if any, this
+ subsystem is currently attached to. If this is -1, then the
+ subsystem is not attached to any hierarchy, and all tasks should be
+ considered to be members of the subsystem's top_container. It should
+ be initialized to -1.
+
+- name: should be initialized to a unique subsystem name prior to
+ calling container_register_subsystem. Should be no longer than
+ MAX_CONTAINER_TYPE_NAMELEN
+
+Each container object created by the system has an array of pointers,
+indexed by subsystem id; this pointer is entirely managed by the
+subsystem; the generic container code will never touch this pointer.
+
+3.2 Synchronization
+-------------------
+
+There are two global mutexes used by the container system. The first

+is the manage_mutex, which should be taken by anything that wants to
+modify a container; The second if the callback_mutex, which should be
+taken by holders of the manage_mutex at the point when they actually
+make changes, and by callbacks from lower-level subsystems that want
+to ensure that no container changes occur. Note that memory
+allocations cannot be made while holding callback_mutex.
+
+The callback_mutex nests inside the manage_mutex.
+
+In general, the pattern of use is:
+
+1) take manage_mutex
+2) verify that the change is valid and do any necessary allocations\
+3) take callback_mutex
+4) make changes
+5) release callback_mutex
+6) release manage_mutex
+
+See kernel/container.c for more details.
+
+Subsystems can take/release the manage_mutex via the functions
+container_manage_lock()/container_manage_unlock(), and can
+take/release the callback_mutex via the functions
+container_lock()/container_unlock().
+
+Accessing a task's container pointer may be done in the following ways:
+- while holding manage_mutex
+- while holding callback_mutex
+- while holding the task's alloc_lock (via task_lock())
+- inside an rcu_read_lock() section via rcu_dereference()
+
+3.3 Subsystem API
+--------------------------
+
+Each subsystem should call container_register_subsys() with a pointer
+to its subsystem object. This will store the new subsystem id in the
+subsystem subsys_id field and return 0, or a negative error. There's
+currently no facility for deregestering a subsystem nor for
+registering a subsystem after any containers (other than the default
+"top_container") have been created.
+
+Each subsystem may export the following methods. The only mandatory
+methods are create/destroy. Any others that are null are presumed to
+be successful no-ops.
+
+int create(struct container *cont)
+LL=manage_mutex
+

+The subsystem should set its subsystem pointer for the passed
+container, returning 0 on success or a negative error code. On
+success, the subsystem pointer should point to a structure of type
+container_subsys_state (typically embedded in a larger
+subsystem-specific object), which will be initialized by the container
+system.
+
+void destroy(struct container *cont)
+LL=manage_mutex
+
+The container system is about to destroy the passed container; the
+subsystem should do any necessary cleanup
+
+int can_attach(struct container_subsys *ss, struct container *cont,
+   struct task_struct *task)
+LL=manage_mutex
+
+Called prior to moving a task into a container; if the subsystem
+returns an error, this will abort the attach operation. If a NULL
+task is passed, then a successful result indicates that *any*
+unspecified task can be moved into the container. Note that this isn't
+called on a fork. If this method returns 0 (success) then this should
+remain valid while the caller holds manage_mutex.
+
+void attach(struct container_subsys *ss, struct container *cont,
+   struct container *old_cont, struct task_struct *task)
+LL=manage_mutex & callback_mutex
+
+Called during the attach operation. The subsystem should do any
+necessary work that can be accomplished without memory allocations or
+sleeping.
+
+void post_attach(struct container_subsys *ss, struct container *cont,
+   struct container *old_cont, struct task_struct *task)
+LL=manage_mutex
+
+Called after the task has been attached to the container, to allow any
+post-attachment activity that requires memory allocations or blocking.
+
+void fork(struct container_subsy *ss, struct task_struct *task)
+LL=callback_mutex, maybe read_lock(tasklist_lock)
+
+Called when a task is forked into a container. Also called during
+registration for all existing tasks.
+
+void exit(struct container_subsys *ss, struct task_struct *task)
+LL=callback_mutex
+

```
+Called during task exit
+
+int populate(struct container_subsys *ss, struct container *cont)
+LL=none
+
+Called after creation of a container to allow a subsystem to populate
+the container directory with file entries.  The subsystem should make
+calls to container_add_file() with objects of type cftype (see
+include/linux/container.h for details).  Called during
+container_register_subsys() to populate the root container.  Note that
+although this method can return an error code, the error code is
+currently not always handled well.
+
+void bind(struct container_subsys *ss, struct container *root)
+LL=callback_mutex
+
+Called when a container subsystem is rebound to a different hierarchy
+and root container. Currently this will only involve movement between
+the default hierarchy (which never has sub-containers) and a hierarchy
+that is being created/destroyed (and hence has no sub-containers).

Subject: [PATCH 4/7] containers (V7): Simple CPU accounting container subsystem
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:25 GMT
View Forum Message <> Reply to Message

This demonstrates how to use the generic container subsystem for a
simple resource tracker that counts the total CPU time used by all
processes in a container, during the time that they're members of the
container.

Subject: [PATCH 5/7] containers (V7): Resource Groups over generic containers
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:26 GMT
View Forum Message <> Reply to Message

This patch provides the RG core and numtasks controller as container subsystems, intended as an example of how to implement a more complex resource control system over generic process containers. The changes to the core involve primarily removing the group management, task membership and configfs support and adding interface layers to talk to the generic container layer instead.

Each resource controller becomes an independent container subsystem; the RG core is essentially a library that the resource controllers can use to provide the RG API to userspace. Rather than a single shares and stats file in each group, there's a <controller>_shares and a <controller>_stats file, each linked to the appropriate resource controller.

Subject: [PATCH 6/7] containers (V7): BeanCounters over generic process containers
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:27 GMT
View Forum Message <> Reply to Message

This patch implements the BeanCounter resource control abstraction over generic process containers. It contains the beancounter core code, plus the numfiles resource counter. It doesn't currently contain any of the memory tracking code or the code for switching beancounter context in interrupts.

Currently all the beancounters resource counters are lumped into a single hierarchy; ideally it would be possible for each resource counter to be a separate container subsystem, allowing them to be connected to different hierarchies.

```

+config BEANCOUNTERS
+ bool "Enable resource accounting/control"
+ default n
+ select CONTAINERS
+ help
+   When Y this option provides accounting and allows configuring
+   limits for user's consumption of exhaustible system resources.
+   The most important resource controlled by this patch is unswappable
+   memory (either mlock'ed or used by internal kernel structures and
+   buffers). The main goal of this patch is to protect processes
+   from running short of important resources because of accidental
+   misbehavior of processes or malicious activity aiming to ``kill''
+   the system. It's worth mentioning that resource limits configured
+   by setrlimit(2) do not give an acceptable level of protection
+   because they cover only a small fraction of resources and work on a
+   per-process basis.  Per-process accounting doesn't prevent malicious
+   users from spawning a lot of resource-consuming processes.

Subject: [PATCH 7/7] containers (V7): Container interface to nsproxy subsystem
Posted by Paul Menage on Mon, 12 Feb 2007 08:15:28 GMT

View Forum Message <> Reply to Message

When a task enters a new namespace via a clone() or unshare(), a new
container is created and the task moves into it. Developed by Serge
Hallyn <serue@us.ibm.com>, adapted by Paul Menage <menage@google.com>

```

> - temporarily removed the "release agent" support.

ouch

> ... it can be re-added ... via a kernel thread that periodically polls containers ...

double ouch.

You'll have a rough time selling me on the idea that some kernel thread should be waking up every few seconds, grabbing system-wide locks, on a big honkin NUMA box, for the few times per hour, or less, that a cpuset is abandoned.

Offhand, that sounds mildly insane to me.

And how would this get the edge-triggered, rather than level-triggered, release? In other words, if a new cpuset is created, and marked with the notify_on_release flag, but otherwise not yet used (no child cpusets and no tasks in it) then it is not to be released (removed.) Only children and/or tasks are added, then later removed, is it a candidate for release. I guess you'll need yet another state bit, set when the cpuset is abandoned (last child removed or last pid exits/leaves), and cleared when this kernel thread visits the cpuset to see if it should be removed.

Can you explain to me how this intruded on the reference counting?

I think it could be made smarter than that, e.g. have a workqueue task that's only woken when a refcount does actually reach zero. (I think that waking a workqueue task is something that can be done without too much worry about locks)

>
> Can you explain to me how this intruded on the reference counting?
>

Essentially, it means that anything that releases a reference count on a container needs to be able to trigger a call to the release agent. The reference count is often released at a point when important locks are held, so you end up having to pass buffers into any function that might drop a ref count, in order to store a path to a release agent to be invoked.

In particular, the new container_clone() function can be called during the task fork path; at which point forking a new release_agent process would be impossible, or at least nasty. Additionally, if containers are potentially going to be used for virtual servers, having the release agent run from a top-level process rather than the process context that released the refcount sounds like a sane option.

Paul

Ok - now that you put it like that - it's much more persuasive.

Consider me sold on this aspect of your proposal, until and unless I protest otherwise, which is not likely.

Thanks.

Forgive my confusion, but do we really need two-levels of resource control abstraction here? Why can't resource controllers directly work with containers (just like cpu accounting does)?

Sorry, this turned out to be left over from when I was debugging an initialization problem that required early_printk(). I should have removed it.

You can safely remove it from the patch.

Paul

The generic containers patch represents a pretty low-level view of task grouping - it doesn't try to prescribe how to do accounting, nor exactly what API to present to the user (beyond providing a filesystem-based interface).

Resource controllers certainly can be written directly over it, but equally having additional abstractions to provide a common user API and kernel API for multiple resources is a reasonable goal.

I would imagine that each different resource being controlled would be represented as a container subsystem, which is how I structured the ResGroups example patch - ResGroups becomes a library that provides a common set of file manipulations for different resource controllers, each of which is a containers subsystem. The same could potentially be done for BeanCounters if people wanted.

But the main point of the latter four patches in this series is to illustrate to the various folks writing resource controller systems (and other observers) that this patch provides sufficient features to act as a base for their work. I don't presume to claim that one higher-level resource control abstraction is better than another.

In this particular patch (which is an almost verbatim
extraction/renaming of the generic bits of the cpusets code into
container.c) it probably could - but the main patch that adds the
container_group support would lose it since we use kref to refcount
container_group objects, and hence they're freed when their refcount
reaches zero. RCU is still fine for reading the container_group
pointers, but it's no good for updating them, since by the time you
update it it may no longer be your container_group structure, and may
instead be about to be deleted as soon as the other thread's
rcu_synchronize() completes.

On further reflection, this probably would be safe after all. Since we
don't call put_container_group() in attach_task() until after
synchronize_rcu() completes, that implies that a container_group_get()
from the RCU section would have already completed. So we should be
fine.

I know I'm a bit out of touch, but AIUI the NSProxy *is* the container.
We decided a long time ago that a container was basically just a set of
namespaces, which includes all of the subsystems you mention.

This would suggesting re-write this patchset, part 2 as a "CPUSet
namespace", part 4 as a "CPU scheduling namespace", parts 5 and 6 as
"Resource Limits Namespace" (drop this "BeanCounter" brand), and of
course part 7 falls away.

Sam.

The nsproxy is an implementation detail, actually, and might go away at
any time. But yes we had been talking for quite awhile about sets of
namespaces as containers, so that a vserver would be a container, as
would a lightweight checkpoint/restart job.

> We decided a long time ago that a container was basically just a set of

>
> This would suggesting re-write this patchset, part 2 as a "CPUSet

Well it's an unfortunate conflict, but I don't see where we have any
standing to make Paul change his terminology :)

Lately I've been talking about "Paul's containers", our "namespaces",
and the "namespace container subsystem" in patch 7.

> namespace", part 4 as a "CPU scheduling namespace", parts 5 and 6 as
> "Resource Limits Namespace" (drop this "BeanCounter" brand), and of
> course part 7 falls away.

Part 7 does not fall away, it uses Paul's patchset to start to provide
a management interface for namespaces.

You may have done that, but the CKRM/ResGroups independently decided a
long time ago that the fundamental unit was the resource class, and
the OpenVZ folks decided that the fundamental unit was the
BeanCounter, and the CPUSet folks decided that the fundamental unit
was the CPUSet, etc ... :-)

But there's a lot of common ground between these different approaches,

and potential for synergy, so the point of this patch set is to
provide a unification point for all of them, and a stepping stone for
other new resource controllers and process control modules.

I have no huge problem with changing my terminology in the interest of
wider adoption. "Container" seems like an appropriate name for the
abstraction, and possibly more appropriate than for a virtual server,
but if it was decreed that the only thing stopping the container patch
being merged was that it should be called, say, "Process Sets", I
would happily s/container/pset/g across the entire patchset.

There was a consensus that emerged that resulted in the nsproxy being
included in the kernel. That is why I used "we". What was included
varies greatly from the patch I put forward, as I mentioned.

You missed the point of what I was trying to say. Let me try again.

Originally I too thought that in order to begin on the path of
virtualisation merging we would just make a simple
container/vserver/whatever structure and hang everything off that.

I'll now say the same thing that was said before of my patch, that I
don't think that adding the containers structure inside the kernel adds
anything interesting or useful. In fact, I'd go further to say that
very thing you think is a useful abstraction is locking yourself into
inflexibility. This is what Eric recognised early on and eventually
brought me around to the idea of too.

So, we have the current implementation - individual subsystems are
virtualised, and it is the subsystems that you can see and work with.
You can group together your virtualisation decisions and call that a
container, great.

Ask yourself this - what do you need the container structure for so
badly, that virtualising the individual resources does not provide for?
You don't need it to copy the namespaces of another process ("enter")
and you don't need it for checkpoint/migration. What does it mean to
make a new container? You're making a "nothing" namespace for some
as-yet-unspecified grouping of tasks. That's a great idea for a set of
tightly integrated userland utilities to simplify the presentation to
the admin, but I don't see why you need to enshrine this in the kernel.
Certainly not for any of the other patches in your set as far as I can see.

> But there's a lot of common ground between these different approaches,

That precisely echos my sentiment on my submissions of some 12 months ago.

Sam.

Right.

Which make me wonder why we need task_lock() at all ..I can understand
the need for a lock like that if we are reading/updating multiple words
in task_struct under the lock. In this case, it is used to read/write
just one pointer, isnt it? I think it can be eliminated all-together
with the use of RCU.

I see that cpuset.c uses task_lock to read/write multiple words
(cpuset_update_task_memory_state) ..So yes it is necessary in attach_task() ..

Numfiles is not the most interesting place in beancounters.
Kmemsize accounting is much more important actually.

I have already pointed out the fact that this place
will hurt performance too much. If we have some context
on task this context must
1. be get-ed without any locking
2. be settable to some temporary one without
   locking as well

Unfortunately current containers implementation doesn't
allow all of the above which blocks the rest implementation
of beancounters over them.

Right, but the memory accouting was a much bigger and more intrusive

patch than I wanted to include as an example.

>

Would you also be happy with the restriction that a task couldn't be
moved in/out of a beancounter container by any task other than itself?
If so, the beancounter can_attach() method could simply return false
if current != tsk, and then you'd not need to worry about locking in
this situation.

> 2. be settable to some temporary one without
> locking as well

I thought that we solved that problem by having a tmp_bc field in the
task_struct that would take precedence over the main bc if it was
non-null?

Paul

I know it, but numfile doesn't show how good this
infrastructure is.

I have implementation that moves arbitrary task :)
May be we can do context (container-on-task) handling lockless?

> If so, the beancounter can_attach() method could simply return false

I may not, but this patch contains locking that is not good
even for example.

Of course, but I'm commenting this patchset which doesn't have
this facility.

The example patch is attached. Fits 2.6.20-rc6-mm3.

OK, I've incorporated some of those changes into my patchset.
bc_file_charge() and bc_file_uncharge() are now lockless, and
tmp_exec_bc is supported too.

I've attached the new versions of patch 3 (main multi-user container
support) and patch 7 (beancounters example)

Does that look more like what you'd like to see?

Paul

Containers on their own aren't all that useful, other than for process tracking, so it seemed reasonable to only build containers if there was some subsystem using them. If people wanted to use them for process tracking alone, it could certainly be made an individually-selectable option.

Using the container name is bad and it led to this stupid argument.

The fundamental unit of what we have merged into the kernel is the
namespace. The aggregate of all namespaces and everything is the
container.

Please, please pick a different name so people don't take one look
at your stuff and get confused like Sam did.

For the case of namespaces I don't see how your code makes things
better. I do not see a real problem that you are solving.

I do agree that a common interface to the code and a common set of
infrastructure may help.

Personally until the pid namespace (which includes within it process
groupings) is complete I'm not certain the problem will be concrete
enough to solve. Hopefully we can have a working version of that
shortly.

Eric

What are you defining here as "everything"? If you mean "all things that could be applied to a segregated group of processes such as a virtual server", then "container" seems like a good name for my patches, since it allows you to aggregate namespaces, resource control, other virtualization, etc.

Sam said "the NSProxy *is* the container". You appear to be planning to have some namespaces, possibly not aggregated within the nsproxy (pid namespace?) but are you planning to have some higher-level "container" object that aggregates the nsproxy and the other namespaces? If so, what is it? Does it track process membership, etc? What's the userspace API? In what fundamental ways would it be different from my generic containers patches with Serge Hallyn's namespace subsystem. (If these questions are answered already by designs or code, I'd be happy to be pointed at them).

I guess what it comes down to, is why is an aggregation of namespaces suitable for the name "container", when an aggregation of namespaces and other resource controllers isn't?

What do you think might be a better name for the generic process groups that I'm pushing? As I said, I'm happy to do a simple search/replace on my code to give a different name if that turned out to be the gating factor to getting it merged. But I'd be inclined to leave that decision up to Andrew/Linus.

I'm trying to solve the problem that lots of different folks (including us) are trying to do things that aggregate multiple process into some kind of constrained group, and are all trying to use different and incompatible ways of grouping/tracking those processes.

I agree that namespaces fit slightly less well into this model than

some other subsystems like resource management. But by integrating
with it you'd get automatic access to all the various different
resource controller work that's being done.

The aggregation happens at the task struct when you apply different
pieces to a task we don't need a structure to allow aggregation.

No. A reverse mapping is not needed and is not interesting.
As long as I can walk all processes and ask what namespace are
you in I don't care.

To me at least the interesting part of your work is not the aggregation

portion. But the infrastructure for building the different process
groups.

You seem to be calling your groups of processes lumped together for
one purpose or another a container.

> What do you think might be a better name for the generic process

As we have previously been using the term container is like
application. The end product that the user sees built out of
individual kernel provided components, but not something that exists
in the kernel as such.

We need a term for the non-aggregated case for the individual process
groups we build this out of in your infrastructure. Because you
clearly have more than one kind of process group a set of processes
can belong to.

>> > But there's a lot of common ground between these different approaches,

I don't need to integrate with it to get access to the resource
controller work. The resource controller work applies to a set of
processes. I have a set of processes. I just need to apply the
resource controllers to my set of processes.

At least when we don't talk about the names for these things it
is that simple. Now global names I have issues with because almost
always the global names fall into their own category, but that is

a different story.

Now I have some half backed ideas that might be useful for providing
a better abstraction. But it requires setting down and looking
at the problem in detail, and understanding what people are trying
to accomplish with these things they are building. What subset of
process groups do you find interesting.

All that is necessary to have a group of processes do something
in an unnamed fashion is to hang a pointer off of the task_struct.
That's easy. You are adding a lot more to that, and there is
enough abstraction I haven't been able to easily work my way through
the infrastructure to what is really going on. Admittedly I haven't
looked closely yet.

The term "segregated group of processes" is too vague. Segregated for
what? What is the kernel supposed to do with this information?

> I guess what it comes down to, is why is an aggregation of namespaces

This argument goes away if you just rename these resource groups to
resource namespaces.

Did you like the names I came up with in my original reply?

 - CPUset namespace for CPU partitioning
 - Resource namespaces:
   - cpusched namespace for CPU
   - ulimit namespace for memory
   - quota namespace for disk space
   - io namespace for disk activity
   - etc

>> For the case of namespaces I don't see how your code makes things

Maybe what's missing is a set of helper macros/functions that assist
with writing new namespaces. Perhaps you can give some more examples
and we can consider these on a case by case basis.

Sam.

The generic part of the kernel just keeps track of the fact that
they're segregated (and their children, etc).

It's the clients of this subsystem (virtual servers, resource
controllers) that can decide to give different per-process behaviour
based on the membership of various groups.

> Did you like the names I came up with in my original reply?

>   - etc

This is a strange abuse of the term "namespace".
http://en.wikipedia.org/wiki/Namespace_%28computer_science%29

For the virtual server work that you're doing, namespace is a good term:

pids name processes, hence a pid namespace lets you have multiple
distinct mappings from pids to processes
filenames name files, so a filename (or mount) namespace lets you have
multiple distinct mappings from filenames to files.

For resource QoS control, it doesn't really make sense to talk about
namespaces. We're not virtualizing resources to rename them for
different virtual servers, we're limiting the quality of access to the
resources.

But the semantics of the term "namespace" notwithstanding, you're
equating a virtual server namespace (pid, ipc, uts, mounts, etc) with
a resource controller (memory, I/O, etc) in terms of their place in a
hierarchy, which is something I agree with. All of these subsystems
can be considered to be units that can be associated with groups of
processes; the ultimate grouping of processes is something that we're
both ultimately referring to as a container.

>
> Maybe what's missing is a set of helper macros/functions that assist
> with writing new namespaces.

That's pretty much what my containers patch does - provides a generic
way to associate state (what you're referring to as a namespace) with
groups of processes and a consistent user-space API for manipulating
them.

Paul

How do you currently do that?

>

In that case you can easily use it to just assign one namespace type
to each tree of process groups. The aggregation is something that
other groups find useful, but isn't required for the user to actually
make use of.

>
> You seem to be calling your groups of processes lumped together for

Correct.

>

Yes. That's why my system supports multiple unrelated hierarchies of groups.

Right, you could certainly do the extra work of tying your virtual servers together with resource controllers in userspace. But you'd still need an API to allow those resource controllers to be associated with groups of processes and configured with limits/guarantees, which is one of the main aims of my containers patch.

> Now I have some half backed ideas that might be useful for providing
> a better abstraction. But it requires setting down and looking
> at the problem in detail, and understanding what people are trying
> to accomplish with these things they are building. What subset of
> process groups do you find interesting.

I'm primarily interested in getting something in the kernel that can be used as a base for interesting subsystems that apply behavioural or QoS changes to defined groups of processes. Resource controllers and namespaces seem to be good examples of this, but I can think of useful subsystems for monitoring, permission control, etc.

>
> All that is necessary to have a group of processes do something
> in an unnamed fashion is to hang a pointer off of the task_struct.
> That's easy.

Right, adding a pointer to task_struct is easy. Configuring how/when to not directly inherit it from the parent, or to change it for a running task, or configuring state associated with the thing that the pointer is pointing to, naming that group, and determining which group a given process is assocaited with, is something that's effectively repeated boiler plate for each different subsystem, and which can be accomplished more generically via an abstraction like my containers patch.

> You are adding a lot more to that, and there is

The main thing that I'm adding on top of the operations mentioned in the previous paragraph, which pretty much essentially have to be in the kernel, is the ability to group multiple different subsystems together so that they share the same process->container mappings. Yes,

that is something that could potentially be done from userspace
instead, and just provide an independent tree for each subsystem or
namespace. But there seems to be interest from other parties
(including me) in having kernel support for it.

So those clients can use helper functions to use their own namespaces.
If they happen to group things in the same way they they'll all end up
using the same nsproxy.

I don't necessarily agree with the 'heirarchy' bit. It doesn't have to be so segregated. But I think we already covered that in this thread.

I agree with the comment on the abuse of the term "namespace", though consider that it has already been abused with the term IPC namespaces. We have for some time been using it to refer to groupable entities within the kernel that are associated with tasks, even if they don't involve named entities that clash within a particular domain. But there is always an entity and a domain, and that is the key point I'm trying to make - the features you are putting forward are no different to the examples that we made specifically for the purpose of setting the standard for further features to follow.

We talked about naming a bit before, see http://lkml.org/lkml/2006/3/21/403 and possibly other threads. So, anyway, feel free to flog this old dead horse and suggest different terms. We've all had long enough to think about it since so maybe it's worth it, but with any new term it should be really darned clear that they're essentially the same thing as namespaces, or otherwise be really likable.

Sam.

So make helpers. Macros. Anything, just don't introduce model limitations like the container structure, because we've already got the structure; the nsproxy.

Sam.

OK, but it's much easier to use a hierarchical system as a flat system (just don't create children) than a flat system as a hierarchical system. And others do seem to want a hierarchy for their process groupings.

>
> I agree with the comment on the abuse of the term "namespace", though

That doesn't seem like an abuse to me at all - you're controlling what IPC object a given name (shm_id, sem_id or msg_id) refers to for any given group of processes.

They're very similar, I agree. An important difference is that things like pid/mount namespaces are simply ways of controlling the visibility of existing unix concepts, such as processes or filesystems. You don't need additional configuration to make them useful, as unix already has standard ways of manipulating them.

Things like resource controllers typically require additional configuration to control how much resources each group of processes can consume, etc. Also, it appears to be much more common to want to move tasks between different resource controllers than to move them between different namespaces. (And in order to configure and move, you need to be able to name)

The configuration, naming and movement are the features that my container patch provides on top of the features that nsproxy provides for namespaces.

What you're calling a "namespace", I'm calling a "subsystem state".
Essentially they're the same thing. The important thing that generic
containers provide is a standard way to manipulate "subsystem states"
or "namespaces".

Eric,

what you gain with this patchset is, one very simple container subsystem
can tie a container to a cpu, another can limit it's RSS, and suddenly
you can

 mount -t container -o ns,rss,cpuwhatever ns /container

And each virtual server you create by unsharing can get automatic cpu
and rss controls.

That is worthwhile imo.

Yes, you can do it with an exhaustive trawl of /proc. That can be very expensive on busy machines.

That doesn't tell you what mounts namespace a process is in - it tells you what the process can *view* in the namespace.

>

As I mentioned in another email, nsproxy is fine for things that don't need explicit configuration or reporting, or which already have configuration methods (such as fork(), mount(), etc) available, and which don't need to support movement of processes between different

"namespaces". If it was extended to support the
naming/config/movement, then it would be fine to use it as the
equivalent of a container.

I'd actually be interested in trying to combine my container object
and the nsproxy object into a single concept.

Bah,

Paul, how about s/container/rug/, as in resource usage group?

At least you can be pretty sure that (a) rug won't conflict with any
other computer science therm, and (b) for that exact reason it should be
pretty memorable.

Which specific portion of oom code cares abt container structure being
intact?

If I understand correctly, only cpuset requires this double locking.
More specifically, cpusets cares about walking cpuset->parent list
safely with callback_mutex held correct?

If that is the case, I think we can push container_lock entirely inside
cpuset.c and not have others exposed to this double-lock complexity.
This is possible because cpuset.c (build on top of containers) still has
cpuset->parent and walking cpuset->parent list safely can be made
possible with a second lock which is local to only cpuset.c.

Hope I am not shooting in the dark here!

If we can indeed avoid container_lock in generic code, it will simplify
code like attach_task (for ex: post_attach/attach can be clubbed into one
single callback).

What's the rule to read/write number_of_cpusets? The earlier cpuset code was incrementing/decrementing under callback_mutex, but now we aren't. How safe is that?

The earlier cpuset code also was reading number_of_cpusets w/o the callback_mutex held (atleast in cpuset_zone_allowed_softwall). Is that safe?

It gets used in the lower loop checking for processes whose memory
policies we should be rebinding.

We're still inside manage_mutex, so we guarantee that no-one else is
changing it.

>
> The earlier cpuset code also was reading number_of_cpusets w/o the

Yes, I think so. Unless every memory allocator was to hold a lock for
the duration of alloc_pages(), number_of_cpusets can theoretically be
out of date by the time you're using it. But since the process could
have allocated just before you created the first cpuset and moved it
into that cpuset anywa, it's not really a race (and the consequences
are inconsequential).

It makes sense in the first cpuset patch
(cpusets_using_containers.patch), but should be removed in the second
cpuset patch (multiuser_container.patch). In the 2nd patch, we use this
comparison:

```
 if (task_cs(p) != cs)
  continue;
```

cont variable introduced in the 1st patch essentially becomes unused
after 2nd patch.

Yes, you're right - it could be removed in the 3rd patch.

The callback mutex (which is what container_lock() actually locks) is also used to synchronize fork/exit against subsystem additions, in the event that some subsystem has registered fork or exit callbacks. We could probably have a separate subsystem_mutex for that instead.

Apart from that, yes, it may well be possible to move callback lock entirely inside cpusets.

Why can't manage_mutex itself be used there (to serialize fork/exit callbacks against modification to hierarchy)?

> Apart from that, yes, it may well be possible to move callback lock

> entirely inside cpusets.

Yes, that way only the hierarchy hosting cpusets takes the hit of
double-locking. cpuset_subsys->create/destroy can take this additional lock
inside cpuset.c.

Because manage_mutex can be held for very long periods of time. I
think that a combination of a new lock that's only taken by fork/exit
and register_subsys, plus task_lock (which prevents the current task
from being moved) would be more lightweight.

> inside cpuset.c.

The primary reason for the cpuset double locking, as I recall, was because
cpusets needs to access cpusets inside the memory allocator. A single,
straight forward, cpuset lock failed under the following common scenario:

1) user does cpuset system call (writes some file below /dev/cpuset, e.g.)
2) kernel cpuset code locks its lock
3) cpuset code asks to allocate some memory for some cpuset structure
4) memory allocator tries to lock the cpuset lock - deadlock!

The reason that the memory allocator needs the cpuset lock is to check
whether the memory nodes the current task is allowed to use have changed,
due to changes in the current tasks cpuset.

A secondary reason that the cpuset code needs two locks is because the
main cpuset lock is a long held, system wide lock, and various low
level bits of performance critical code sometimes require quick,
read-only access to cpusets.

"needs to access cpusets" - can you be more specific?

Being able to safely walk cpuset->parent list - is it the only access
you are talking of or more?

Never mind. Maneesh pointed me to do_rmdir() in VFS which takes that
mutex as well.

Does this check break existing namespace semantics in a subtle way?
It now requires that unshare() of namespaces by any task requires
CAP_SYS_ADMIN capabilities.

clone(.., CLONE_NEWUTS, ..)->copy_namespaces()->ns_container_clone()->
 ->container_clone()-> .. -> container_create() -> ns_create()

Earlier, one could unshare his uts namespace w/o CAP_SYS_ADMIN
capabilities. Now it is required. Is that fine? Don't know.

I feel we can avoid this check totally and let the directory permissions
take care of these checks.

Serge, what do you think?

```

This is probably carrying over code from cpuset.c, but :

/me thinks that there is a ugly race here with 'tsk' exiting.
What happens if the tsk is marked PF_EXITING just after this check?
If that happens, then:

```
> +   read_unlock(&tasklist_lock);
> +   return -ESRCH;
> +  }
> +
> +  get_task_struct(tsk);
> +  read_unlock(&tasklist_lock);

> +  put_task_struct(tsk);
> +  return -ESRCH;
> + }
> + atomic_inc(&cont->count);
> + rcu_assign_pointer(tsk->container, cont);
```

Above assignment A1 can race with below assignment A2 in container_exit() :

```
 tsk->container = &top_container; /* the_top_container_hack - see above */
```

What happens if A1 follows after A2? I feel very uncomfortable abt it.

IMO, we need to use task_lock() in container_exit() to avoid this race.

(I think this race already exists in mainline cpuset.c?)

P.S : cpuset.c checks for PF_EXITING twice in attach_task(), while this
patch seems to be checking only once. Is that fine?

I think the cpuset code is ok, because, as you note, it locks the task,
picks off the cpuset pointer, and then checks a second time that the
task still does not have PF_EXITING set:

In the kernel/cpuset.c code for attach_task():

```
        task_lock(tsk);
        oldcs = tsk->cpuset;
        /*
         * After getting 'oldcs' cpuset ptr, be sure still not exiting.
         * If 'oldcs' might be the top_cpuset due to the_top_cpuset_hack
         * then fail this attach_task(), to avoid breaking top_cpuset.count.
         */
        if (tsk->flags & PF_EXITING) {
                task_unlock(tsk);
                mutex_unlock(&callback_mutex);
                put_task_struct(tsk);
                return -ESRCH;
        }
```

Well afaics, PF_EXITING is set for the exiting task w/o taking any lock, which
makes this racy always.

> In the kernel/cpuset.c code for attach_task():

What if PF_EXITING is set after this check? If that happens then,

> task_unlock(tsk);
> mutex_unlock(&callback_mutex);
> put_task_struct(tsk);
> return -ESRCH;
> }

the following code becomes racy with cpuset_exit() ...

```
atomic_inc(&cs->count);
rcu_assign_pointer(tsk->cpuset, cs);
task_unlock(tsk);
```

eh ... so ... ?

I don't know of any sequence where that causes any problem.

Do you see one?

> Do you see one?

Let's say we had two cpusets CS1 amd CS2 (both different from top_cpuset).
CS1 has just one task T1 in it (CS1->count = 0) while CS2 has no tasks
in it (CS2->count = 0).

Now consider:

```
 ------------------------------------------------------------ --------
CPU0 (attach_task T1 to CS2)   CPU1 (T1 is exiting)
 ------------------------------------------------------------ --------

task_lock(T1);

oldcs = tsk->cpuset;
[oldcs = CS1]

T1->flags & PF_EXITING? (No)

     T1->flags = PF_EXITING;

atomic_inc(&CS2->count);

     cpuset_exit()
        cs = tsk->cpuset; (cs = CS1)

T1->cpuset = CS2;

         T1->cpuset = &top_cpuset;

task_unlock(T1);
```

CS2 has one bogus count now (with no tasks in it), which may prevent it from
being removed/freed forever.

Not just this, continuing further we have more trouble:

```
 ------------------------------------------------------------ --------
CPU0 (attach_task T1 to CS2)   CPU1 (T1 is exiting)
 ------------------------------------------------------------ --------

synchronize_rcu()
         atomic_dec(&CS1->count);
         [CS1->count = 0]

if atomic_dec_and_test(&oldcs->count))
```

[CS1->count = -1]

We now have CS1->count negative. Is that good? I am uncomfortable ..

We need a task_lock() in cpuset_exit to avoid this race.

2nd race is tricky. We probably need to do this to avoid it:

```
task_lock(tsk);

/* Check if tsk->cpuset is still same. We may have raced with
 * cpuset_exit changing tsk->cpuset again under our feet.
 */
if (tsk->cpuset == cs && atomic_dec_and_test(&oldcs->count)) {
 task_unlock(tsk);
        check_for_release(oldcs, ppathbuf);
```

```
 goto done;
}

 task_unlock(tsk);

done:
 return 0;
```

vatsa wrote:
> Now consider:

Nice work - thanks. Yes, both an extra cpuset count and a negative
cpuset count are bad news, opening the door to the usual catastrophes.

Would you like the honor of submitting the patch to add a task_lock
to cpuset_exit()? If you do, be sure to fix, or at least remove,
the cpuset_exit comment lines:

```
 * We don't need to task_lock() this reference to tsk->cpuset,
 * because tsk is already marked PF_EXITING, so attach_task() won't
 * mess with it, or task is a failed fork, never visible to attach_task.
```

I guess that taking task_lock() in cpuset_exit() should not be a serious
performance issue. It's taking a spinlock that is in the current
exiting tasks task struct, so it should be a cache hot memory line and
a rarely contested lock.

And I guess I've not see this race in real life, as one side of it has
to execute quite a bit of code in the task exit path, from when it sets
PF_EXITING until it gets into the cpuset_exit() call, while the other side
does the three lines:

```
 if (tsk->flags & PF_EXITING) ...
 atomic_inc(&cs->count);
 rcu_assign_pointer(tsk->cpuset, cs);
```

So, in real life, this would be a difficult race to trigger.

Thanks for finding this.

I will try to send out a patch later today to fix this bug in mainline
cpuset code. I happened to notice this race with my rcfs patch and observed
same is true with cpuset/container code also.

Sure, I had seen that.

I'm unsure here, but this 'tsk->cpuset == cs' test feels fragile to me.

How about a bit earlier in attach_task(), right at the point we overwrite the victim tasks cpuset pointer, we decrement the count on the old cpuset, and if it went to zero, remember that we'll need to release it, once we've dropped some locks:

```
static int attach_task(struct cpuset *cs, char *pidbuf, char **ppathbuf)
{
 ...
 struct cpuset *oldcs;
 struct cpuset *oldcs_tobe_released;

 ...

        task_lock(tsk);
        oldcs = tsk->cpuset;
        ...
        if (tsk->flags & PF_EXITING) {
                ...
        }
        atomic_inc(&cs->count);
        rcu_assign_pointer(tsk->cpuset, cs);
 oldcs_tobe_released = NULL;
 if (atomic_dec_and_test(&oldcs->count))
  oldcs_tobe_released = oldcs;
        task_unlock(tsk);

 ...
 put_task_struct(tsk);
        synchronize_rcu();
        if (oldcs_tobe_released)
                check_for_release(oldcs_tobe_released, ppathbuf);
        return 0;
}
```

Looks neater. Will adopt this when I send the patch. Thanks.

Not so, CAP_SYS_ADMIN is required. Depending on your tree, check
kernel/utsname.c or kernel/nsproxy.c.

Mind you, whether there is a reason to require CAP_SYS_ADMIN for utsname
I'm not sure. But if there is any way of finding privileged software
which would behave differently based on utsname information, then we
should.

There is no way we can think about doing that until we determine that
every kernel will have the ns container subsystem compiled in and
mounted, right?

That is still not true, see kernel/utsname:copy_utsname().

Now you might have run a userspace testcase in a kernel with
CONFIG_UTS_NS=n, which at the moment erroneously returns 0 rather than
-EINVAL when you clone(CLONE_NEWUTS). But you didn't get a new uts
namespace, you were just lied to :)

I think you are right here, in that CONFIG_UTS_NS was not turned on,
although I was thinking it was on.

However as a result of this experiment, I found this anomaly:

- On a kernel with CONFIG_UTS_NS=n, a test which does
  clone(CLONE_NEWUTS) works fine. clone() succeeds and the child
  starts running with no error.
- On the same kernel, if ns container hierarchy is mounted, then
  the test fails. clone() returns failure and child is never created.
  As soon as the ns container hierarchy is unmounted, the test works
  again.

I would have expected a consistent behavior here, irrespective of
whether ns hierarchy is mounted or not. Is this difference in behavior
acceptable? Returning -EINVAL in copy_utsname() when CONFIG_UTS_NS=n, as
you say above, would fix this anomaly.

This function is a no-op if ns hierarchy is not mounted at this point.
This would mean that we will miss out on some directories in ns
hierarchy if it happened to be mounted later. It would be nice to
recreate such missing directories upon mount. However I suspect it would
not be easy ..Maybe we need to scan the task list and (re-)invoke
ns_container_clone() for every new tsk->nsproxy we find in the list.
Alternately perhaps we could auto mount (kern_mount) ns hierarchy very early at
bootup? On the flip side that would require remount support so that additional
controllers (like cpuset, mem) can be bound to (non-empty) ns hierarchy after
bootup.

Losing the directory isn't a big deal though. And both unsharing a
namespace (which causes a ns_container_clone) and mounting the hierarchy
are done by userspace, so if for some installation it is a big deal,
the init scripts on initrd can mount the hierarchy before doing any
unsharing.

Can you think of a reason why losing a few directories matters?
