Subject: [RFC][PATCH][0/4] Memory controller (RSS Control)
Posted by Balbir Singh on Mon, 19 Feb 2007 06:50:19 GMT
View Forum Message <> Reply to Message

This patch applies on top of Paul Menage's container patches (V7) posted at

http://lkml.org/lkml/2007/2/12/88

It implements a controller within the containers framework for limiting
memory usage (RSS usage).

The memory controller was discussed at length in the RFC posted to lkml
http://lkml.org/lkml/2006/10/30/51

Steps to use the controller
---

0. Download the patches, apply the patches
1. Turn on CONFIG_CONTAINER_MEMCTLR in kernel config, build the kernel
   and boot into the new kernel
2. mount -t container container -o memctlr /<mount point>
3. cd /<mount point>
   optionally do (mkdir <directory>; cd <directory>) under /<mount point>
4. echo $$ > tasks (attaches the current shell to the container)
5. echo -n (limit value) > memctlr_limit
6. cat memctlr_usage
7. Run tasks, check the usage of the controller, reclaim behaviour
8. Report bugs, get bug fixes and iterate (goto step 0).

Advantages of the patchset
---

1. Zero overhead in struct page (struct page is not expanded)
2. Minimal changes to the core-mm code
3. Shared pages are not reclaimed unless all mappings belong to overlimit
   containers.
4. It can be used to debug drivers/applications/kernel components in a
   constrained memory environment (similar to mem=XXX option), except that
   several containers can be created simultaneously without rebooting and
   the limits can be changed. NOTE: There is no support for limiting
   kernel memory allocations and page cache control (presently).

Testing

Ran kernbench and lmbench with containers enabled (container filesystem not
mounted), they seemed to run fine
Created containers, attached tasks to containers with lower limits than

the memory the tasks require (memory hog tests) and ran some basic tests on
them

TODO's and improvement areas
---
1. Come up with cool page replacement algorithms for containers
   (if possible without any changes to struct page)
2. Add page cache control
3. Add kernel memory allocator control
4. Extract benchmark numbers and overhead data

Comments & criticism are welcome.

Subject: [RFC][PATCH][1/4] RSS controller setup
Posted by Balbir Singh on Mon, 19 Feb 2007 06:50:26 GMT
View Forum Message <> Reply to Message

This patch sets up the basic controller infrastructure on top of the
containers infrastructure. Two files are provided for monitoring
and control memctlr_usage and memctlr_limit.

memctlr_usage shows the current usage (in pages, of RSS) and the limit
set by the user.

memctlr_limit can be used to set a limit on the RSS usage of the resource.
A special value of 0, indicates that the usage is unlimited. The limit
is set in units of pages.

Subject: [RFC][PATCH][2/4] Add RSS accounting and control
Posted by Balbir Singh on Mon, 19 Feb 2007 06:50:34 GMT
View Forum Message <> Reply to Message

This patch adds the basic accounting hooks to account for pages allocated
into the RSS of a process. Accounting is maintained at two levels, in
the mm_struct of each task and in the memory controller data structure

associated with each node in the container.

When the limit specified for the container is exceeded, the task is killed.
RSS accounting is consistent with the current definition of RSS in the
kernel. Shared pages are accounted into the RSS of each process as is
done in the kernel currently. The code is flexible in that it can be easily
modified to work with any definition of RSS.

Subject: [RFC][PATCH][3/4] Add reclaim support
Posted by Balbir Singh on Mon, 19 Feb 2007 06:50:42 GMT
View Forum Message <> Reply to Message

This patch reclaims pages from a container when the container limit is hit.
The executable is oom'ed only when the container it is running in, is overlimit
and we could not reclaim any pages belonging to the container

A parameter called pushback, controls how much memory is reclaimed when the
limit is hit. It should be easy to expose this knob to user space, but
currently it is hard coded to 20% of the total limit of the container.

isolate_lru_pages() has been modified to isolate pages belonging to a
particular container, so that reclaim code will reclaim only container
pages. For shared pages, reclaim does not unmap all mappings of the page,
it only unmaps those mappings that are over their limit. This ensures
that other containers are not penalized while reclaiming shared pages.

Parallel reclaim per container is not allowed. Each controller has a wait
queue that ensures that only one task per control is running reclaim on
that container.

Signed-off-by: <balbir@in.ibm.com>

+Introduction
+------------
+
+The memory controller is a controller module written under the containers
+framework. It can be used to limit the resource usage of a group of
+tasks grouped by the container.
+
+Accounting
+----------
+
+The memory controller tracks the RSS usage of the tasks in the container.
+The definition of RSS was debated on lkml in the following thread
+
+ http://lkml.org/lkml/2006/10/10/130
+
+This patch is flexible, it is easy to adapt the patch to any definition
+of RSS. The current accounting is based on the current definition of
+RSS. Each page mapped is charged to the container.
+
```

+The accounting is done at two levels, each process has RSS accounting in
+the mm_struct and in the container it belongs to. The mm_struct accounting
+is used when a task switches (migrates to a different) container(s). The
+accounting information for the task is subtracted from the source container
+and added to the destination container. If as result of the migration, the
+destination container goes over limit, no action is taken until some task
+in the destination container runs and tries to map a new page in its
+page table.
+
+The current RSS usage can be seen in the memctlr_usage file. The value
+is in units of pages.
+
+Control
+-------
+
+The memctlr_limit file allows the user to set a limit on the number of
+pages that can be mapped by the processes in the container. A special
+value of 0 (which is the default limit of any new container), indicates
+that the container can use unlimited amount of RSS.
+
+Reclaim
+-------
+
+When the limit set in the container is hit, the memory controller starts
+reclaiming pages belonging to the container (simulating a local LRU in
+some sense). isolate_lru_pages() has been modified to isolate lru
+pages belonging to a specific container. Parallel reclaims on the same
+container are not allowed, other tasks end up waiting for the any existing
+reclaim to finish.
+
+The reclaim code uses two internal knobs, retries and pushback. pushback
+specifies the percentage of memory to be reclaimed when the container goes
+over limit. The retries knob, controls how many times reclaim is retried
+before the task is killed (because reclaim failed).
+
+Shared pages are treated specially during reclaim. They are not force
+reclaimed, they are only unmapped from containers which are over limit.
+This ensures that other containers do not pay a penalty for a shared
+page being reclaimed when a paritcular container goes over its limit.
+
+NOTE: All limits are hard limits.
+
+Future Plans
+------------
+
+The current controller implements only RSS control. It is planned to add
+the following components
+

+1. Page Cache control
+2. mlock'ed memory control
+3. kernel memory allocation control (memory allocated on behalf of a task)

It's good to see someone building on someone else's work for once, rather
than everyone going off in different directions. It makes one hope that we
might actually achieve something at last.

The key part of this patchset is the reclaim algorithm:

> + if (container && !page_in_container(page, zone, container)) {
> +   scan--;
> +   goto done;
> + }

Alas, I fear this might have quite bad worst-case behaviour. One small
container which is under constant memory pressure will churn the
system-wide LRUs like mad, and will consume rather a lot of system time.
So it's a point at which container A can deleteriously affect things which
are running in other containers, which is exactly what we're supposed to

not do.

The patches use the identifier "memctlr" a lot. It is hard to remember,
and unpronounceable. Something like memcontrol or mem_controller or
memory_controller would be more typical.

> ...
>
> + BUG_ON(!mem);
> + if ((buffer = kmalloc(nbytes + 1, GFP_KERNEL)) == 0)
> + return -ENOMEM;

Please prefer to do

 buffer = kmalloc(nbytes + 1, GFP_KERNEL);
 if (buffer == NULL)
  reutrn -ENOMEM;

ie: avoid the assign-and-test-in-the-same-statement thing. This affects
the whole patchset.

Also, please don't compare pointers to literal zero like that. It makes me
get buried it patches to convert it to "NULL". I think this is a sparse
thing.

> +  goto out_unlock;
> +
> + spin_lock(&mem->lock);
> + mem->counter.limit = limit;
> + spin_unlock(&mem->lock);
```

The patches do this a lot: a single atomic assignment with a pointless-looking lock/unlock around it. It's often the case that this idiom indicates a bug, or needless locking. I think the only case where it makes sense is when there's some other code somewhere which is doing

```
 spin_lock(&mem->lock);
 ...
 use1(mem->counter.limit);
 ...
 use2(mem->counter.limit);
 ...
 spin_unlock(&mem->lock);
```

where use1() and use2() expect the two reads of mem->counter.limit to return the same value.

Is that the case in these patches? If not, we might have a problem in there.

```

```

> +   s - usagebuf);
> +}

This output is hard to parse and to extend. I'd suggest either two
separate files, or multi-line output:

usage: %lu kB
limit: %lu kB

and what are the units of these numbers? Page counts? If so, please don't
do that: it requires appplications and humans to know the current kernel's
page size.

But here we treat zero as an error?

ah-ha, we have another Documentation/SubmitChecklist customer.

It would be more conventional to make this return -EFOO on error,
zero on success.

> +void memctlr_mm_free(struct mm_struct *mm)

More weird locking here.

```
> +void memctlr_mm_assign_container(struct mm_struct *mm, struct task_struct *p)
> +{
> + struct container *cont = task_container(p, &memctlr_subsys);
> + struct memctlr *mem = memctlr_from_cont(cont);
> +
> + BUG_ON(!mem);
> + write_lock(&mm->container_lock);
> + mm->container = cont;
> + write_unlock(&mm->container_lock);
> +}
```

And here.

```
> +/*
> + * Update the rss usage counters for the mm_struct and the container it belongs
> + * to. We do not fail rss for pages shared during fork (see copy_one_pte()).
> + */
> +int memctlr_update_rss(struct mm_struct *mm, int count, bool check)

> + cont = mm->container;
> + read_unlock(&mm->container_lock);
> +
> + if (!cont)
> +  goto done;
```

And here. I mean, if there was a reason for taking the lock around that
read, then testing `cont' outside the lock just invalidated that reason.

```
> +static inline void memctlr_double_lock(struct memctlr *mem1,
> +      struct memctlr *mem2)

> +}
```

Conventionally we take the lower-addressed lock first when doing this, not
the higher-addressed one.

Again, please use zero for success and -EFOO for error.

That way, you don't have to assume that the reason memctlr_update_rss()
failed was out-of-memory. Just propagate the error back.

This one doesn't get checked?

Why does MEMCTLR_DONT_CHECK_LIMIT exist?

I spy a compile error.

The static-inline version looks nicer.

Usually one doesn't need to put ifdefs around the declaration like this.
If the function doesn't exist and nobody calls it, we're fine. If someone
does call it, we'll find out the error at link-time.

```

This all looks a bit racy. And that's common in memory reclaim. We just have to ensure that when the race happens, we do reasonable things.

I suspect the locking in here could simply be removed.

I think it's OK for a container to consume lots of system time during reclaim, as long as we can account that time to the container involved (i.e. if it's done during direct reclaim rather than by something like kswapd).

Churning the LRU could well be bad though, I agree.

Paul

Nice with a simple memory controller. The downside seems to be that it doesn't scale very well when it comes to reclaim, but maybe that just comes with being simple. Step by step, and maybe this is a good first step?

Ideally I'd like to see unmapped pages handled on a per-container LRU with a fallback to the system-wide LRUs. Shared/mapped pages could be handled using PTE ageing/unmapping instead of page ageing, but that may consume too much resources to be practical.

/ magnus

Two separate files would be the container usage model that I envisaged, inherited from the way cpusets does things.

And in this case, it should definitely be the limit in one file, readable and writeable, and the usage in another, probably only readable.

Having to read a file called memctlr_usage to find the current limit sounds wrong.

Hmm, I don't appear to have documented this yet, but I think a good naming scheme for container files is <subsystem>.<whatever> - i.e. these should be memctlr.usage and memctlr.limit. The existing grandfathered Cpusets names violate this, but I'm not sure there's a lot we can do about that.

>
> Clean up the first file here?

Containers don't currently provide an API for a subsystem to clean up
files from a directory - that's done automatically when the directory
is deleted.

I think I'll probably change the API for container_add_file to return
void, but mark an error in the container itself if something goes
wrong - that way rather than all the subsystems having to check for
error, container_populate_dir() can do so at the end of calling all
the subsystems' populate methods.

hmm, is it ok to scan 100Gb of RAM for 10MB RAM container?
in UBC patch set we used page beancounters to track containter pages.
This allows to make efficient scan contoler and reclamation.

Thanks,
Kirill

I don't mean that we shouldn't go for the most efficient method that's practical. If we can do reclaim without spinning across so much of the LRU, then that's obviously better.

But if the best approach in the general case results in a process in the container spending lots of CPU time trying to do the reclaim, that's probably OK as long as we can account for that time and (once we have a CPU controller) throttle back the container in that case. So then, a container can only hurt itself by thrashing/reclaiming, rather than hurting other containers. (LRU churn notwithstanding ...)

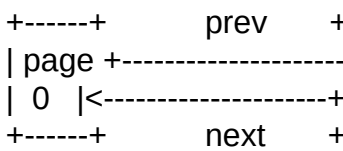
Hmm.. I guess it's space vs time then :-) A CPU controller could
control how much time is spent reclaiming ;)

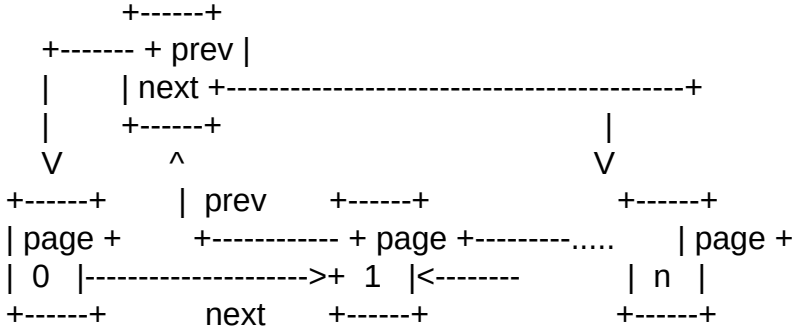
Coming back, I see the problem you mentioned and we have been thinking
of several possible solutions. In my introduction I pointed out

> "Come up with cool page replacement algorithms for containers
> (if possible without any changes to struct page)"

The solutions we have looked at are

1. Overload the LRU list_head in struct page to have a global
   LRU + a per container LRU





Page 1 and n belong to the same container, to get to page 0, you need
two de-references

2. Modify struct page to point to a container and allow each container to
   have a per-container LRU along with the global LRU

For efficiency we need the container LRU and we don't want to split
the global LRU either.

We need to optimize the reclaim path, but I thought of that as a secondary
problem. Once we all agree that the controller looks simple, accounts well
and works. We can/should definitely optimize the reclaim path.

The next set of patches move to atomic values for the limits. That should
fix the locking.

Yes, this looks much better. I'll move to this format. I get myself lost
in "bc" at times, that should have been a hint.

```
>> +static struct cftype memctlr_usage = {
>> + .name = "memctlr_usage",

>
> Clean up the first file here?
>
```

I used cpuset_populate() as an example to code this one up.
I don't think there is an easy way in containers to clean up
files. I'll double check

```
>> +  return rc;
>> + return 0;
>> +}
>> +
>> +static struct container_subsys memctlr_subsys = {

Hi, Kirill,

Yes, that's a problem, but I think it's a problem that can be solved
in steps. First step, add reclaim. Second step, optimize reclaim.

I completely agree with you on reclaim consuming time.

Churning the LRU can be avoided by the means I mentioned before

1. Add a container pointer (per page struct), it is also
   useful for the page cache controller
2. Check if the page belongs to a particular container before
   the list_del(&page->lru), so that those pages can be skipped.
3. Use a double LRU list by overloading the lru list_head of
   struct page.

Keeping unmapped pages per container sounds interesting. I am not quite
sure what PTE ageing, will it look it up.

It's a read_lock() and most of the locks are read_locks
which allow for concurrent access, until the container
changes or goes away

```

The locking is mostly to ensure that tasks belonging to the same container
see a consistent value of reclaim_in_progress. I'll see if the locking
can be simplified or simply removed.

```

I did not want to expose struct container in mm/vmscan.c. An additional
thought was that no matter what container goes in the field would be
useful for reclaim.

read_lock isn't free, and I suspect we're calling this function pretty
often (every pagefault?) It'll be measurable on some workloads, on some
hardware.

It probably won't be terribly bad because each lock-taking is associated
with a clear_page(). But still, if there's any possibility of lightening
the locking up, now is the time to think about it.

Am having trouble parsing that sentence ;)

Why <subsystem>.<whatever>, dots are harder to parse using regular
expressions and sound DOS'ish. I'd prefer "_" to separate the
subsystem and whatever :-)

It should be easy to add container_remove_file() instead of marking
an error.

Yes, good point. I'll revisit to see if barriers can replace the locking
or if the locking is required at all?

Yes, true

The thought was that irrespective of the infrastructure that goes in
having an entry for reclaim in scan_control would be useful. I guess
the name exposes what the type tries to hide :-)

You will most likely have no luck looking it up, so here is what I
mean by PTE ageing:

The most common unit for memory resource control seems to be physical
pages. Keeping track of pages is simple in the case of a single user
per page, but for shared pages tracking the owner becomes more
complex.

I consider unmapped pages to only have a single user at a time, so the
unit for unmapped memory resource control is physical pages. Apart
from implementation details such as fun with struct page and
scalability, handling this case is not so complicated.

Mapped or shared pages should be handled in a different way IMO. PTEs
should be used instead of using physical pages as unit for resource
control and reclaim. For the user this looks pretty much the same as

physical pages, apart for memory overcommit.

So instead of using a global page reclaim policy and reserving physical pages per container I propose that resource controlled shared pages should be handled using a PTE replacement policy. This policy is used to keep the most active PTEs in the container backed by physical pages. Inactive PTEs gets unmapped in favour over newer PTEs.

One way to implement this could be by populating the address space of resource controlled processes with multiple smaller LRU2Qs. The compact data structure that I have in mind is basically an array of 256 bytes, one byte per PTE. Associated with this data strucuture are start indexes and lengths for two lists. The indexes are used in a FAT-type of chain to form single linked lists. So we create active and inactive list here - and we move PTEs between the lists when we check the young bits from the page reclaim and when we apply memory pressure. Unmapping is done through the normal page reclaimer but using information from the PTE LRUs.

In my mind this should lead to more fair resource control of mapped pages, but if it is possible to implement with low overhead, that's another question. =)

Thanks for listening.

Thanks for explaining PTE aging.

"_" is useful for names with "spaces". Names like mem_controller. "."
seems reasonable despite its regex nastyness. Alternatively there's
always ":".
