It looks like a bunch of driver/module issues I've been having are boiling down to different versions of gcc, with me using 3.4 and you guys using 3.3. How do I compile my kernel with 3.4?

You can use compat-gcc-33 and fill the bug with gcc 3.4 compile errors in order to get them fixed in following kernels.

Basically you have two options:

1. Use compat-gcc-33 to compile your kernel module. I assume something like this will do the trick:

```
yum install compat-gcc-33  
make CC=gcc33
```

2. Rebuild our kernel with your default GCC version:

```
rpmbuild --rebuild --target=i686 ovzkernel*.src.rpm
```

If you use x86_64, fix --target argument accordingly (or do not use it at all as this will be a default on that platform).

I think that finally did the trick.
