---

Hey guys,

I'm not the smartest tool in the shed with OpenVZ, but I have tried everything with this problem. I'm running Pentium D 3.4 GhZ, with 2 GB RAM, and 160 GB Hard Drive. I'm using HyperVM as well. My kernel panics often, three times a day sometimes - and tells me theres so many kernel bugs. I know for sure this isn't a hardware issue, so please tell me what could be to blame. I just installed the version of OpenVZ that comes with HyperVM. If you guys need any info, let me know. Also - the RAM will fill to 99.9% with cache, not utilize swap - and crash. (panic)

If you guys need logs or anything relevant - let me know

Regards,  
Joe

(I'm on CentOS 4.4 by the way)

As a tech who tried to fix issue, server rises in load after it reports a kernel bug. See the latest ones. I did a custom compile of kernel, version 2.6.18. For me, it looks like a faulty memory, but server owner said, he replaced every hardware.

Mar 19 02:45:29 localhost kernel: Process exim (pid: 22837, veid: 120, ti=f3d0f000 task=f38446e0 task.ti=f3d0f000)

=====

With this above kernel bug, server load started rising and finally all VPSes stopped responding. I was not able to do a 'vzctl stop veid" or a "vzctl exec 120 kill -9 22837" or even to enter the vps "vzctl enter 120". It simply hangs there and finally have to do Ctrl + C to get the shell prompt back. BTW that exim process raised the load to 100+ before I issued a reboot.

Please shed some lights into this issue. I am going clueless. I dont want to think it is kernel bug, but what are our other options to try ?

Hello, we need the following information from you:

- 1) what is the kernel version you're using? You've renamed the kernel to 2.6.18-028, so we don't know the version of kernel sources you have used to compile the kernel.
- 2) We need the .config file you've used to compile the kernel.

Thank you,  
Vasily.

I used both the available rpms at openvz kernel repo.

For the source compilation, I used the kernel config ,  
[http://download.openvz.org/kernel/devel/028test018.1/configs /kernel-2.6.18-i686-smp.config.ovz](http://download.openvz.org/kernel/devel/028test018.1/configs/kernel-2.6.18-i686-smp.config.ovz)

and the patch at [http://download.openvz.org/kernel/devel/028test018.1/patches /](http://download.openvz.org/kernel/devel/028test018.1/patches/)

Hmmm... It is very strange, that you have so much bugs on such widely used kernel. This makes me think, that the problem is in hardware. Can you, please, test hardware:  
[http://wiki.openvz.org/Hardware\\_testing?](http://wiki.openvz.org/Hardware_testing?) If there will be no corruptions, we'll create a BUG.

Thank you,  
Vasily.

yeah that's what I wonder. I already ran memtester. But (it may be the reason) it crashed the server and owner asked not to run it again. I confirmed with him that he has replaced the RAM a week back and already the entire server itself.

Results of running memtester on 1024 out of the total 2048 gave me the following results.  
mapcount went negative here, which I doubted corrupt RAM and that's why asked owner about the RAM replacement and he said he did it.

last line is what I got, before it crashed.

memtester 1024M  
memtester version 4.0.6 (32-bit)  
Copyright (C) 2006 Charles Cazabon.  
Licensed under the GNU General Public License version 2 (only).

pagesize is 4096  
pagesizemask is 0xffff000  
want 1024MB (1073741824 bytes)  
got 1024MB (1073741824 bytes), trying mlock ...locked.

I guess, you should convince the owner to run memtest on the new node again. At the moment there is a huge amount of broken memory on market, and it's quite possible that the second node is also broken. Frankly speaking each production node should be tested before installing OS there.

Thank you,  
Vasily
