I've come across this how-to article regarding the concept of NIC Bonding or Grouping and wanted to know if OVZ supports that kind of setup. Here's a link to the article:

http://howtoforge.com/nic_bonding#comment-3628

Here's an excerpt from the article:

"The concept of NIC Bonding (or sometimes called NIC Teaming) is that you have two NICs bonded together to appear as if they are the same physical device. I.e. They will both present the same Hardware (MAC) address. This is accomplished through the ifenslave utility, which enables the kernel to see/use only one device, while it sends out packets via the two slave devices using a round-robin scheduler."

You can use bonding on HN with OpenVZ, but it isn't possible to use bond device inside VE.

HTH,
Vasily

Is this still the case that we can't use the bond interface inside the VE?

Thanks.
