
Subject: Kernel text size with the pid namespaces fixes
Posted by [Pavel Emelianov](#) on Tue, 25 Sep 2007 11:00:49 GMT
[View Forum Message](#) <> [Reply to Message](#)

Hi, Suka

I have posted tree patches with un-inlining of some macros and static inline calls that are expanded into another call.

At my i386 notebook this saved about half-a-kilo from the vmlinux. Could you please check these patches at your boxes/configs to see how much progress we have here.

Here's the combined patch for 2.6.24-rc8-mm1

Thanks,
Pavel

on my qemu configuration, scripts/bloat-o-meter gave the following results.

it would be interesting to run some micro benchmark. Did you have time to do that ?

Thanks,

C.

We did. We ran an nptl test and it showed no performance degradation.
 This was expected - I didn't introduce new "call"-s in this patch. See,

all the uninline macros called some function at the end. I just moved the whole code (with the preparations) into a call.

I see you have an interesting effect as well. Look, if you generate the .i file for mm/swapfile.c (the one where sys_swapoff is) for two cases - with and without this patch - you will see that the .i files differ in one place only - the find_task_xxx calls have transformed from macros into extern calls and (!) no places in this sys_swapoff() use them.

The question is - WHY its size changed?
Why gcc produces different code on the same input?

BTW, you're lucky - your sys_swapoff shrank, but mine grew up just like yours msg_exit_ns() which has nothing to do with the functions changed :(
