Hi

Why does vzsplrit create config files that allow overcommitment of memory (allocation of memory that is) even when the -s 0 switch is used to ignore swap space?

I ran the command, vzsplrit -n 25 -s0, created a VE based on this config, and the output of vzcalc is below:

Resource	Current(%)	Promised(%)	Max(%)
Low Mem	0.18	4.20	4.20
Total RAM	1.86	n/a	n/a
Mem + Swap	0.87	1.90	n/a
Alloc. Mem	1.88	1.90	8.15
Num. Proc	0.03	n/a	1.14

IF alloc mem if =~8% then 25*8% is 200% allocation!

Where do you see 8%?

8.15 in Max column for Alloc. Mem

Makes sense to me. It will allow up to 8% of the memory, only if it is available. Overcommitted would be to allow 8% of guaranteed.

We believe that memory allocation overcommit is safe, because usually applications do not use all the allocated memory:
