The HN (CentOS 5) works correctly. I tried to mount nfs and it's OK. The VE (CentOS 5 as well) works fine but I cannot mount nfs.

I followed the HowTo (<http://wiki.openvz.org/NFS>). The command:

vzctl exec 182215 cat /proc/filesystems gives:

```
.....ext2
.....ext3
nodev  autofs
nodev  rpc_pipefs
nodev  nfs
nodev  proc
nodev  sysfs
nodev  tmpfs
nodev  devpts
```

But from within the VE, the command:

mount -t nfs abpc10303:/local /mnt gives the error:

mount: wrong fs type, bad option, bad superblock on abpc10303:/local,

.....missing codepage or other error

.....In some cases useful info is found in syslog - try

.....dmesg | tail or so

Of course, there is nothing written in /var/log/messages of VE, HN and the NFS server.

Does anybody have an idea about the error? Maybe there is an obvious reason, but I can't find it...

Hello

1) what kernel/vzctl do you use?

2) may be it makes sense to provide the codepage as an explicit option to the mount?

3) did you check only /var/log/messages? Can you please also check "dmesg" inside the VE, VE0 and nfs server.

Thank you.

- 1) VE kernel version: 2.6.18-53.el5.028stab051.1. vzctl version: 3.0.22.
- 2) The man page about mount says this can be done when the file system is FAT or VFAT. But I use ext3 everywhere.
- 3) Syslogd is running on VE, VE0 (the HN OS, right?) and NFS server, but /var/log/dmesg files did not register anything about the mount attempt (file times are hours ago).

Thank you for your fast reply, Konstantin.

There is no /usr/sbin/rpc.mountd. The portmap program is running correctly.

So it is a problem of installation! I'm going to check the OS template...

Hi,

Try to install nfs-utils inside VPS. I hope this must help you.

Please show the output of the following:

- rpm -qa | grep nfs (from HN and VPS)
- rpm -qf /bin/mount (from HN and VPS)

What exactly osteamplate do you use?

Thank You!

Sorry to answer so lately. I'm implied on several projects so I'm not working much on each.

It was a template problem cause I have CentOS 5 minimal and default files and for the VE I was working on, I installed the minimal version.

How is it possible to know the template name the VE is based on?

Anyway, thanks to all of those who replied to my questions.

Hi,

In VE conf file
`grep -i OSTEMPLATE /etc/vz/conf/<VE_ID>.conf`
